Figure 9-8.—Basic VFR weather minimums.

Table 9-1.—Basic VFR weather minimums.

Altitude	Flight visibility	Distance from clouds
1,200 feet or less above the surface (regardless of MSL altitude)—		
Within controlled airspace.	3 statute miles. . .	500 feet below. 1,000 feet above. 2,000 feet horizontal.
Outside controlled airspace.	1 statute mile (except as in 91.105(B)). . . .	Clear of clouds.
More than 1,200 feet above the surface but less than 10,000 feet MSL—		
Within controlled airspace.	3 statute miles. . .	500 feet below. 1,000 feet above. 2,000 feet horizontal.
Outside controlled airspace.	1 statute mile . . .	500 feet below. 1,000 feet above. 2,000 feet horizontal.
More than 1,200 feet above the surface and at or above 10,000 feet MSL.	5 statute miles. . .	1,000 feet below. 1,000 feet above. 1 mile horizontal.

91.107 Special VFR weather minimums.

(a) Except as provided in FAR 93.113 (Control zones within which special VFR weather minimums are not authorized), when a person has received an appropriate ATC clearance, the special weather minimums of this section instead of those contained in 91.105 apply to the operation of an aircraft by that person in a control zone under VFR.

(b) No person may operate an aircraft in a control zone under VFR except clear of clouds.

(c) No person may operate an aircraft (other than a helicopter) in a control zone under VFR unless flight visibility is at least 1 statute mile.

(d) No person may takeoff or land an aircraft (other than a helicopter) at any airport in a control zone under VFR—

(1) Unless ground visibility at that airport is at least 1 statute mile; or

(2) If ground visibility is not reported at that airport, unless the flight visibility during landing or takeoff is at least 1 statute mile.

91.109 VFR cruising altitude or flight level.

Except while holding in a holding pattern of 2 minutes or less, or while turning, each person operating an aircraft under VFR in level cruising flight, at or above 3,000 feet above the surface, shall maintain the appropriate altitude prescribed below:

(a) When operating below 18,000 feet MSL and—

(1) On a magnetic course of zero degrees through 179 degrees, any odd thousand foot MSL altitude +500 feet (such as 3,500, 5,500, or 7,500); or

(2) On a magnetic course of 180 degrees through 359 degrees, any even thousand foot MSL altitude +500 feet (such as 4,500, 6,500, or 8,500).

(b) When operating above 18,000 feet MSL to flight level 290 (inclusive), and—

(1) On a magnetic course of zero degrees through 179 degrees, any odd flight level +500 feet (such as 195, 215, or 235); or

(2) On a magnetic course of 180 degrees through 359 degrees, any even flight level +500 feet (such as 185, 205, or 225).

(c) When operating above flight level 290 and—

(1) On a magnetic course of zero degrees through 179 degrees, any flight level, at 4,000 foot intervals, beginning at and including flight level 300 (such as flight level 300, 340, or 380); or

(2) On a magnetic course of 180 degrees through 359 degrees, any flight level at 4,000-

AC.129

Figure 9-9.—Cruising altitudes.

foot intervals, beginning at and including flight level 320 (such as flight level 320, 360, or 400). (See fig. 9-9.)

Instrument Flight Rules

91.115 ATC clearance and flight plan required.

No person may operate an aircraft in controlled airspace under IFR unless—

(a) He has filed an IFR flight plan; and

(b) He has received an appropriate ATC clearance

91.116 Takeoff and landing under IFR.

(a) Instrument approaches to civil airports. Unless otherwise authorized by the Administrator (including ATC), each person operating an aircraft shall, when an instrument letdown to an airport is necessary, use a standard instrument approach procedure prescribed for that airport in Part 97.

(b) Landing minimums. Unless otherwise authorized by the Administrator, no person operating an aircraft (except a military aircraft of the United States) may land that aircraft using a standard instrument approach procedure prescribed in FAR Part 97 unless the visibility is at or above the landing minimum prescribed in FAR 97 for the procedure used. If the landing minimum in a standard instrument approach procedure prescribed in FAR 97 is stated in terms of ceiling and visibility, the visibility minimum applies. However, the ceiling minimum shall be added to the field elevation and that value observed as the MDA or DH, as appropriate to the procedure being executed.

(c) Civil airport takeoff minimums. Unless otherwise authorized by the Administrator, no person operating an aircraft under FAR 121, 123, 129, or 135 (commercial aircraft operators including foreign) may takeoff from a civil airport under IFR unless weather conditions are at or above the weather minimums for IFR takeoff prescribed for that airport in FAR 97. If takeoff minimums are not prescribed in FAR 97, for a particular airport, the following minimums apply to takeoffs under IFR for aircraft operating as described above:

(1) Aircraft having two engines or less: 1 statute mile visibility.

(2) Aircraft having more than two engines: 1/2 statute mile visibility.

(d) Military airports. Unless otherwise prescribed by the Administrator, each person operating a civil aircraft under IFR into, or out of a military airport shall comply with the instrument approach procedure and the takeoff and landing minimums prescribed by the military authority having jurisdiction on that airport.

(e) Comparable values of VFR and ground visibility. If RVR minimums for takeoff or landing are prescribed in an instrument approach procedure, but RVR is not reported for the runway of intended operation, the RVR minimum shall be converted to ground visibility in accordance with the following comparable values and observed as the applicable visibility minimum for takeoff or landing on that runway:

RVR	Visibility (statute miles)
1,600 feet	1/4 mile
2,400 feet	1/2 mile
3,200 feet	5/8 mile
4,000 feet	3/4 mile
4,500 feet	7/8 mile
5,000 feet	1 mile
6,000 feet	1 1/4 mile

(f) Use of radar in any instrument approach procedure. When radar is approved at certain locations for ATC purposes, it may be used not only for surveillance and precision radar approaches, as applicable, but also may be used in conjunction with instrument approach procedures predicated on other types of radio navigation aids. Radar vectors may be authorized to provide course guidance through the segments of an approach procedure to final approach fix or position. Upon reaching the final approach fix or position, the pilot will either complete his instrument approach in accordance with the procedure approved for the facility, or will continue a surveillance or precision radar approach to a landing.

(g) Limitations on procedure turns. In the case of a radar initial approach to a final approach fix or position, or a timed approach from a holding fix, or where the procedure specifies NOPT or FINAL, no pilot may make a procedure turn unless, when he receives his final approach clearance, he so advises ATC.

91.117 Limitations on the use of instrument approach procedures.

(a) Unless otherwise authorized by the Administrator, each person operating an aircraft using an instrument approach procedure prescribed in FAR 97 shall comply with the requirements of this section.

(b) Descent below MDA or DH. No person may operate an aircraft below the prescribed minimum descent altitude or continue an approach below the decision height unless—

(1) The aircraft is in a position from which a normal approach to the runway of intended landing can be made; and

(2) The approach threshold of that runway, or approach lights or other markings identifiable with the approach end of that runway, are clearly visible to the pilot. If, upon arrival at the missed approach point or decision height, or at any time thereafter, any of the above requirements are not met, the pilot shall immediately execute the appropriate missed approach procedure.

91.119 Minimum altitudes for IFR operations.

(a) Except when necessary for takeoff or landing, or unless otherwise authorized by the Administrator, no person may operate an aircraft under IFR below—

(1) The applicable minimum altitudes prescribed in Parts 95 and 97; or

(2) If no applicable minimum altitude is prescribed in those Parts—

(i) In the case of operations over an area designated as a mountainous area in Part 95, an altitude of 2,000 feet above the highest obstacle within a horizontal distance of 5 statute miles from the course to be flown; or

(ii) In any other case, an altitude of 1,000 feet above the highest obstacle within a horizontal distance of 5 statute miles from the course to be flown. However, if both a MEA and a MOCA are prescribed for a particular route or route segment, a person may operate an aircraft below the MEA down to, but not below, the MOCA, when within 25 statute miles of the VOR concerned (based on the pilot's reasonable estimate of that distance).

(b) Climb. Climb to a higher minimum IFR altitude shall begin immediately after passing the point beyond which that minimum altitude applies, except that, when ground obstructions intervene the point beyond which the higher minimum altitude applies shall be crossed at or above the applicable MCA.

91.121 IFR cruising altitude or flight level.

(a) In controlled airspace. Each person operating an aircraft under IFR in level cruising flight in controlled airspace shall maintain the altitude or flight level assigned that aircraft by ATC. However, if the ATC clearance assigns "VFR conditions-on-top," he shall maintain an altitude or flight level as prescribed by 91.109.

(b) In uncontrolled airspace. Except while holding in a holding pattern of 2 minutes or less, or while turning, each person operating an aircraft under IFR in level cruising flight, in uncontrolled airspace, shall maintain an appropriate altitude as follows:

(1) When operating below 18,000 feet MSL and—

(i) On a magnetic course of zero degrees through 179 degrees, any odd thousand foot MSL altitude (such as 3,000, 5,000, or 7,000); or

(ii) On a magnetic course of 180 degrees through 359 degrees, any even thousand foot MSL altitude (such as 2,000, 4,000, or 6,000).

(2) When operating at or above 18,000 feet MSL but below flight level 290, and—

(i) On a magnetic course of zero degrees through 179 degrees, any odd flight level (such as 190, 210 or 230); or

(ii) On a magnetic course of 180 degrees through 359 degrees, any even flight level (such as 180, 200, or 220).

(3) When operating at flight level 290 and above, and—

(i) On a magnetic course of zero degrees through 179 degrees, any flight level, at 4,000-foot intervals, beginning at and including flight level 290 (such as flight level 290, 330, or 370); or

(ii) On a magnetic course of 180 degrees through 359 degrees, any flight level, at 4,000-foot intervals, beginning at and including flight level 310 (such as flight level 310, 350, or 390). (See fig. 9-9.)

91.123 Course to be flown.

Unless otherwise authorized by ATC, no person may operate an aircraft within controlled airspace, under IFR, except as follows:

(a) On a Federal airway, along the centerline of that airway.

(b) On any other route, along the direct course between the navigational aids or fixes defining that route.

However, this section does not prohibit maneuvering the aircraft to pass well clear of other air traffic or the maneuvering of the aircraft,

10586 10586

in VFR conditions, to clear the intended flight path both before and during climb or descent.

91.125 IFR, radio communications.

The pilot in command of each aircraft operated under IFR in controlled airspace shall have a continuous watch maintained on the appropriate frequency and shall report by radio as soon as possible—

(a) The time and altitude of passing each designated reporting point, or the reporting points specified by ATC, except that while the aircraft is under radar control, only the passing of those reporting points specifically requested by ATC need be reported;

(b) Any unforecast weather conditions encountered; and

(c) Any other information relating to the safety of flight.

91.127 IFR operations; two-way radio communications failure.

(a) General. Unless otherwise authorized by ATC, each pilot who has two-way radio communications failure when operating under IFR shall comply with the rules of this section.

(b) VFR Conditions. If the failure occurs in VFR conditions, or if VFR conditions are encountered after the failure, each pilot shall continue the flight under VFR and land as soon as practicable.

(c) IFR Conditions. If the failure occurs in IFR conditions, or if paragraph (b) of this section cannot be complied with, each pilot shall continue the flight according to the following:

(1) Route.

(i) By the route assigned in the last ATC clearance received;

(ii) If being radar vectored by the direct route from the point of radio failure to the fix, route, or airway specified in the vector clearance;

(iii) In the absence of an assigned route, by the route that ATC has advised may be expected in a further clearance; or

(iv) In the absence of an assigned route or a route that ATC has advised may be expected in a further clearance, by the route filed in the flight plan.

(2) Altitude. At the highest of the following altitudes or flight levels:

(i) The altitude or flight level assigned in the last ATC clearance received;

(ii) The minimum altitude (converted, if appropriate, to minimum flight level as prescribed in 91.81 (c)) for IFR operations; or

(iii) The altitude or flight level ATC has advised may be expected in a further clearance.

(3) Climb. When it is necessary to climb in order to comply with subparagraph (2) of this paragraph, the following applies;

(i) Climb to the assigned altitude or flight level in accordance with the last ATC clearance received;

(ii) Climb to the minimum altitude for IFR operation at the time or place necessary to comply with that minimum; or

(iii) Climb to the altitude or flight level ATC has advised may be expected in a further clearance at the time or place included in the expect-further-clearance.

(4) Leave holding fix. If holding instructions have been received, leave the holding fix at the expect-further-clearance time received, or, if an expected approach clearance time has been received, leave the holding fix in order to arrive over the fix from which the approach begins as close as possible to the expected approach clearance time.

(5) Descent. Begin descent from the en route altitude or flight level upon reaching the fix from which the approach begins, but not before—

(i) The expect-approach-clearance time (if received); or

(ii) If no expect-approach-clearance time has been received, at the estimated time of arrival, shown on the flight plan, as amended with ATC.

91.129 Operation under IFR in controlled airspace; malfunction reports.

(a) The pilot in command of each aircraft operated in controlled airspace under IFR, shall report immediately to ATC any of the following malfunctions of equipment occurring in flight:

(1) Loss of VOR, TACAN, ADF, or low frequency navigation receiver capability.

(2) Complete or partial loss of ILS receiver capability.

(3) Impairment of air/ground communications capability.

(b) In each report required by paragraph (a) of this section, the pilot in command shall include the—

(1) Aircraft identification;

10587 10588

(2) Equipment affected;

(3) Degree to which the capability of the pilot to operate under IFR in the ATC system is impaired; and

(4) Nature and extent of assistance he desires from ATC.

FAR PART 95—IFR ALTITUDES

95.1 Applicability.

(a) This part prescribes altitudes governing the operation of aircraft under IFR on Federal airways, jet routes, or other direct routes for which an MEA is designated in this part. In addition, it designates mountainous areas and changeover points (not included in this training manual).

(b) The MAA is the highest altitude on a Federal airway, jet route, or other direct route for which an MEA is designated in this part at which adequate reception of navigation aid signals is assured.

(c) The MCA applies to the operation of an aircraft proceeding to a higher minimum en route altitude when crossing specified radio fixes.

(d) The MEA prescribed for a Federal airway or segment thereof, applies to the entire width of that airway or segment between the radio fixes defining that airway or segment. An MEA prescribed for an off-airway route or route segment applies to the airspace 5 statute miles on each side of a direct course between radio fixes defining that route or route segment. The MEA in effect between fixes assures navigation signal reception and obstruction clearance between those fixes.

(e) The MOCA applies to the operation of an aircraft within 25 statute miles of the VOR station concerned. The MOCA assures obstruction clearance between the fixes specified but adequate reception of navigational signals is assured only within 25 miles of the VOR station concerned.

(f) The MRA applies to the operation of an aircraft over an intersection used in the navigation of that aircraft. The MRA is the lowest altitude at which the intersection can be determined.

(g) The COP (changeover point) applies to operation of an aircraft along a Federal airway, jet route, or other direct route for which an MEA is designated in this part. It is the most appropriate point for transfer of the airborne navigation reference between the facility abaft the aircraft and the next appropriate facility along the Federal airway, jet route, or other direct route that provides:

(1) Continuous reception between facilities; and

(2) A common source of azimuth guidance for all aircraft operating along the same segment of the Federal airway, jet route, or direct route.

FAR, PART 99—SECURITY CONTROL OF AIR TRAFFIC

99.1 Applicability.

(a) This subpart prescribes rules for operating civil aircraft in a defense area, or into, within, or out of the United States through an Air Defense Identification Zone (ADIZ).

(b) Except for 99.7, this subpart does not apply to the operation of an aircraft—

(1) In a Coastal or Domestic ADIZ north of 28 degrees north latitude or west of 85 degrees west longitude at a true airspeed of less than 180 knots;

(2) In the Alaskan DEWIZ at a true airspeed of less than 180 knots while the pilot maintains a continuous listening watch on the appropriate frequency;

(3) From any point in the 48 contiguous States on an outbound track through the Southern Border ADIZ that does not penetrate a Coastal ADIZ;

(4) Within the 48 contiguous States and the District of Columbia, or within the State of Alaska, which remains within 10 nautical miles of the point of departure; or

(5) Over any island, or within three nautical miles of the coastline of any island, in the Hawaiian ADIZ.

(c) Except as provided in 99.7, the radio and position reporting requirements of this subpart do not apply to the operation of an aircraft within the 48 contiguous States and the District of Columbia, or within the State of Alaska, if that aircraft does not have two-way radio and is operated in accordance with a filed DVFR flight plan containing the time and point of Domestic or Coastal ADIZ penetration and that aircraft departs within five minutes of the estimated departure time contained in the flight plan.

(d) An FAA ATC center may exempt the following operations from this subpart (except

10588

99.7), on a local basis only, with the concurrence of the military commanders concerned:

(1) Aircraft operations that are conducted wholly within the boundaries of an ADIZ and are not currently significant to the air defense system.

(2) Aircraft operations conducted in accordance with special procedures prescribed by the military authorities concerned.

99.3 General.

(a) Air defense identification zones (ADIZ's) are areas of airspace over land or water in which the ready identification, location, and control of civil aircraft is required in the interest of national security. (See fig. 9-10.) They are classified as—

(1) Coastal air defense identification zones (Coastal ADIZ's);

(2) Domestic air defense identification zones (Domestic ADIZ's); and

(3) Distant early warning identification zones (DEWIZ's).

(b) Unless designated as an ADIZ, a Defense Area is any airspace of the United States in which the control of aircraft is required for national security.

(c) For the purposes of this Part, a Defense Visual Flight Rules (DVFR) flight is a flight within an ADIZ conducted under the visual flight rules in Part 91.

AC.130

Figure 9-10.—ADIZ's and defense area.

determination. Slope of the trailing edge causes the receiver to remain blanked longer than necessary, reducing minimum range performance and target resolution.

Noise may also affect the shape of the pulse, thereby affecting the accuracy of range measurements. Figure 15-1 illustrates a typical pulse shape with a pulse corrupted by noise superimposed (shown by the dotted line). The time delay from transmitted pulse to received echo will be shortened by the amount Δt.

Notice that if the rise and fall times were zero, noise would affect only the amplitude of the pulse and would not affect range accuracy. For large signal to noise ratios, the slope of the pulse plus noise is the same as the slope of the uncorrupted pulse.

PULSE REPETITION FREQUENCY

The pulse repetition frequency (PRF) largely determines the maximum range and, to some degree, the accuracy of a radar set. The actual time elapsing between the beginning of one pulse and the beginning of the next, called the pulse repetition period, is the reciprocal of the PRF. Thus, for example, if the PRF is 400 cycles per second, the pulse repetition period is 1/400 seconds, or 2,500 microseconds. When the PRF is too high—that is, when the period between pulses is too short—the echo from the farthest target may return to the receiver after the transmitter has emitted another pulse, making it impossible to tell whether the observed pulse is the echo of the pulse just transmitted or the echo of the preceding pulse. Such a condition is referred to as range ambiguity.

Although the pulse repetition rate must be kept low enough to attain the required maximum range, it must also be kept high enough to avoid some of the pitfalls a single pulse might encounter. If a single pulse were sent out by a transmitter, atmospheric conditions might attenuate it, the target might not reflect it properly, or moving parts—such as a propeller—might throw it out of phase or change its shape. Thus, information derived from a single pulse would be highly unreliable; but by sending many pulses, one after another, many good ones will return. The equipment will integrate or sum up the good points of all the pulses and present you with a clear, reliable picture. Equipment is therefore designed in such a way that many pulses (10 or more) are received from a single object. In this way, effects of fading are somewhat reduced. At short ranges the repetition frequency is increased in order to insure accurate measurements. Many echoes are received from one target, and the integrating effect is increased.

Figure 15-1. —Noise distorted radar pulse.

Tactical employment of a radar set determines, to a large degree, the PRF to be used. Long range search sets require a pulse rate slow enough to allow echoes from targets at the maximum range to return to the receiver before the transmitter is again pulsed. Higher pulse rates are used in aircraft interception sets where the maximum range is less.

The following equation will readily determine either the PRF or the range if one of them is known:

$$\text{PRF} = \frac{\text{Speed of Light}}{2 \times \text{Range}}$$

(Multiplying range by 2 converts range to radar range.) Thus a radar with a PRF of 800 cycles per second could operate to a maximum range of about 100 miles without range ambiguity. Most radar equipments use 2,000 yards as the standard radar mile; the difference between it and the nautical mile (6,076 feet) is approximately 1 percent.

In theory it is desirable to strike a target with as many pulses of energy as possible during a given scan. Thus, the higher the PRF the better. A high PRF combined with a narrow pulse improves angular resolution and range rate accuracy by sampling the position of the target more often. However, we have shown that maximum range limits the PRF.

99.5 Emergency situations.

In an emergency that requires immediate decision and action for the safety of the flight, the pilot in command of an aircraft may deviate from the rules in this Part to the extent required by that emergency. He shall report the reasons for the deviation to the communications facility where flight plans or position reports are normally filed (referred to in this Part as "an appropriate aeronautical facility") as soon as possible.

99.7 Special security instructions.

Each person operating an aircraft in an ADIZ or Defense Area shall, in addition to the applicable operating rules of this Part, comply with special security instructions issued by the Administrator or in the interest of national security and consistent with appropriate agreements between the FAA and Department of Defense.

The special security instructions referred to in the above paragraph is the plan for the Security Control of Air Traffic and Air Navigation Aids (short title: SCATANA). This plan is distributed in the Navy as OpNav Instruction 3722.30. This plan defines the responsibilities of the Administrator, and the appropriate military authorities for the security control of civil and military air traffic and Federal air navigation aids. It defines the responsibility of the Federal Communications Commission (FCC) for the security control of non-Federal civil air navigation aids. It describes the situations which concern national security, and the necessary action to be taken. It also provides for testing the plan at least once every 60 days. Air Controlmen should study OpNav Instruction 3722.30 as all control tower personnel will become involved in an actual implementation of the plan or the frequent test procedures.

99.9 Radio requirements.

No person may operate an aircraft in an ADIZ unless the aircraft has a functioning two-way radio.

99.11 Flight plan requirements; Coastal or Domestic ADIZ.

(a) No person may operate an aircraft in or penetrating a Coastal or Domestic ADIZ unless he has filed a flight plan with an appropriate aeronautical facility.

(b) Unless ATC authorizes an abbreviated flight plan—

(1) A flight plan for IFR flight must contain the information specified in 91.83; and

(2) A flight plan for VFR flight must contain the information specified in 91.83 (a) (1) through (7).

(c) The pilot shall designate a flight plan for VFR flight as a DVFR flight plan.

99.13 Flight plan requirements; DEWIZ.

(a) No person may operate an aircraft in or penetrating a DEWIZ unless he has filed a flight plan before takeoff with an appropriate aeronautical facility. If there is no facility for filing a DVFR flight plan, the pilot must comply with 99.25 (a) (2) and proceed according to the instructions issued by the appropriate aeronautical facility. These instructions normally require the flight to proceed to a specific area for visual identification or to land at a stated location.

(b) Unless ATC authorizes an abbreviated flight plan—

(1) A flight plan for IFR flight must contain the information specified in 91.83 and the estimated time and point of DEWIZ penetration (ETDP); and

(2) A flight plan for VFR flight must contain the information in 91.83 (a) (1) through (7) and the estimated time and point of DEWIZ penetration (ETDP).

(c) The pilot shall designate a flight plan for VFR flight as a DVFR flight plan.

99.15 Arrival or completion notice.

The pilot in command of an aircraft for which a flight plan has been filed shall file an arrival or completion notice with an appropriate aeronautical facility, unless the flight plan states that no notice will be filed.

99.17 Position reports; aircraft operating in or penetrating a Domestic ADIZ; IFR.

The pilot of an aircraft operating in or penetrating a Domestic ADIZ under IFR—

(a) In controlled airspace, shall make the position reports required in 91.125; and

10590

153 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

(b) In uncontrolled airspace, shall make the position reports required in 99.19.

99.19 Position reports; aircraft operating in or penetrating a Domestic ADIZ; DVFR.

No pilot may penetrate a Domestic ADIZ under DVFR unless—

(a) He reports to an appropriate aeronautical facility before penetration: The time, position, and altitude at which the aircraft passed the last reporting point before penetration and the estimated time of arrival over the next appropriate reporting point along the flight route;

(b) If there is no appropriate reporting point along the flight route, he reports at least 15 minutes before penetration: The estimated time, position, and altitude at which he will penetrate; or

(c) If the airport of departure is so close to the Domestic ADIZ boundary that it prevents his complying with paragraphs (a) or (b) of this section, he has reported immediately after taking off: The time of departure, altitude, and estimated time of arrival over the first reporting point along the flight route.

99.21 Position reports; aircraft entering the United States through a Coastal ADIZ; United States aircraft.

The pilot of an aircraft entering the United States through a Coastal ADIZ shall make the reports required in 99.17 or 99.19 to an appropriate aeronautical facility.

99.23 Position reports; aircraft entering the United States through a Coastal ADIZ; foreign aircraft.

In addition to such other reports as ATC may require, no pilot in command of a foreign civil aircraft may enter the United States through a Coastal ADIZ unless he makes the reports required in 99.17 or 99.19 or reports the position of the aircraft when it is not less than one hour and not more than two hours average direct cruising distance from the United States.

99.25 Position reports; aircraft entering the United States through a DEWIZ.

(a) The pilot of an aircraft entering the United States through a DEWIZ—

(1) If under IFR, shall report his position as required by 91.125; or

(2) If under DVFR, shall report when within radio range of an appropriate aeronautical facility but before penetration: The time, altitude, and position at which he passed the last reporting point and the estimated time, altitude and point of penetration.

(b) If requested, the pilot of an aircraft entering the United States through a DEWIZ shall advise an appropriate aeronautical facility of the difference between the actual time and point of penetration and the same data recorded in the original ground filed flight plan.

99.27 Deviation from flight plans and ATC clearance and instructions.

(a) No pilot may deviate from the provisions of an ATC clearance or ATC instruction except in accordance with 91.75 of this chapter.

(b) No pilot may deviate from his filed IFR flight plan when operating an aircraft in uncontrolled airspace unless he notifies an appropriate aeronautical facility before deviating.

(c) No pilot may deviate from his filed DVFR flight plan unless he notifies an appropriate aeronautical facility before deviating.

99.29 Radio failure; DVFR.

If the pilot operating an aircraft under DVFR in an ADIZ cannot maintain two-way radio communications, he may proceed in accordance with his original DVFR flight plan or land as soon as practicable. The pilot shall report the radio failure to an appropriate aeronautical facility as soon as possible.

99.31 Radio failure; IFR.

If a pilot operating an aircraft under IFR in an ADIZ cannot maintain two-way radio communications, he shall proceed in accordance with 91.127 of this chapter.

99.33 Flight plans: Panama Canal Zone Domestic ADIZ.

Civil aircraft may operate within the Panama Canal Zone Domestic ADIZ only under a flight plan that has been proved by appropriate military authority acting through an FAA air traffic control facility.

10591 10290

CHAPTER 10

AIR TRAFFIC CONTROL COMMUNICATIONS

Consider the vital link supplied by communications between controllers and air traffic. Without such communications, the controller is severely limited to approval or disapproval of anticipated air traffic movements and then only when visual contact exists, such as with the traffic control light as illustrated in chapter 4 of this training manual. It stands to reason that such an important tool deserves considerable attention from the controller. Existing communications equipment at naval control facilities is relatively simple to operate; however, correct application of the simple or basic procedures is a prerequisite to reliable communications when engaged in air traffic control. This chapter is intended to provide the AC with the fundamental knowledge necessary for the correct use of communications and equipment.

RADIO PROCEDURE

RECEIVER CHECK

It is a generally accepted practice to check all receivers at least once during each watch to be sure that they are operating. Logically the oncoming watch will do this upon relieving the offgoing watch to determine the usability of the equipment. This may be accomplished by making short transmissions on each assigned frequency at one operating position with all receivers OFF at that position but ON at another position to monitor the check transmission. In actuality, both the transmitters and receivers are being checked by this method since no reception of the check transmission on a particular frequency could indicate a malfunction of either the transmitter or receiver. In the event a malfunction is indicated, controllers should notify the technicians who make further checks and repairs where necessary.

VOLUME ADJUSTMENT

NOTE: The Phone Level, Speaker Level, Mic Level controls, and VU meter referred to in this section are illustrated in chapter 4 of this training manual on the FSA-17 and FSA-52 communications equipment.

Volume adjustment is an individual operation in that each controller has his own desired level of volume. The basic requirement to consider, however, is that volume is not reduced to the extent that transmissions from aircraft within your area of responsibility might not be heard. Conditions affecting volume adjustment vary also. If a controller is monitoring only one frequency and is using a headset, then volume adjustment consists only of adjustment of the Phone Level control for a comfortable listening level in the headphone. If a speaker is used, then the Speaker Level control is adjusted for a reasonable listening level but not louder than absolutely necessary, so as not to disturb other controllers at different operating positions. In the case of overhead speakers in the tower, the Speaker Level control is usually physically located in the equipment room and once the levels are set at a comfortable level they are left in that position. However, there will be times when a controller will want more volume, in which case someone has to go to the equipment room and make the adjustment.

Along with volume control, the Mic Level control should be set for proper modulation of the transmitters. To accomplish this, set all radiophone switches in the OFF position, depress the Mic switch, and speak into the microphone in a normal conversational manner. Vary the Mic Level control until the majority of the peak swings on the VU meter needle pass just above the zero level on the meter. This will properly modulate the transmitters and set the level for the interphone circuits.

10592

FREQUENCY MONITORING

Radiofrequencies are assigned to naval facilities by appropriate military authority, each for a particular function. Monitoring procedure differs between facilities; however, the normal procedure at most continuously manned facilities is to monitor all tower and approach control frequencies on a continuous basis. At certain operating positions, such as approach control where the operator normally uses a headset, the receivers may be switched to a speaker and the volume increased during periods of light or no traffic.

RADIO DISCIPLINE AND SECURITY

Radio discipline is defined as including the maintenance and proper use of radio equipment, the adherence to prescribed procedure when operating, and employment of remedial action when and where necessary.

Air Controlmen are particularly concerned with the portions of radio discipline having to do with the proper use of equipment and adherence to prescribed procedures. Radio discipline is not only an essential factor in communication security, but an essential for efficient and reliable communications. Standard radio procedures contribute to rapid and accurate communications and relieve the various channels of unnecessary congestion. Message phraseology must be as brief as possible consistent with intelligibility and understandability. Messages should, however, be adequately worded so that they are understood the first time they are transmitted. For this reason certain words are sometimes included in standard messages which may appear unnecessary. They contribute sufficiently to intelligibility and understandability to make their use desirable. In wording radio-telephone messages, the best rules are: First, be sure it will be understood on the first transmission; and second, be brief.

Judgment must be used in the employment of the phonetic alphabet, even though it is an excellent aid when properly used. There is no advantage in using it for transmission of abbreviations when words for which the abbreviations stand can be transmitted as easily and as intelligibly. For example, controllers and pilots are sometimes heard transmitting, "India Foxtrot Romeo Flight Plan," when instrument flight or IFR flight plan would actually be more quickly understood.

Security may not always seem to be such an important factor in peacetime. Radio security, however, cannot be routinely disregarded and then be resumed overnight with the beginning of hostilities. It must be practiced at all times so that it causes no distraction at a time when immediate attention is required by many other things.

A radio transmission, like the spoken word, once uttered can never be recalled. It must be assumed that the enemy intercepts every transmission made. Therefore, give as little information as possible. Transmission security is that part of communication security which is the controller's responsibility.

Just as there is an antidote for every poison, for every tool of warfare an effective countermeasure is usually developed. To prevent the enemy from learning the truth through his observation of our radio activity, the principles of transmission security have been developed. These principles are grouped into four categories—deception, interference, silence, and discipline. Discipline has just been discussed.

Deception is the means by which the enemy is misinformed to drive him into a trap; he is encouraged to draw the wrong conclusions, and he is generally thrown off balance. The enemy analyzes our traffic; and by studying the volume of traffic and the direction of flow, he attempts to predict what move we are planning.

Radio silence is one of the most effective ways of keeping information from the enemy, and it must be observed carefully. During radio silence it is imperative that no radio transmission be made.

Interference properly executed can prevent the enemy from communicating efficiently and possibly cause such confusion and disorganization of his activities that it might affect the tide of battle. One must be alert to change frequencies quickly, if the enemy is attempting to interfere with the transmission, and deliver the message before the enemy has time to discover the new frequency.

As a guide, there are general regulations and additional local regulations governing things one can or cannot do on the air. One of the important rules which must be followed everywhere is that no transmission is made which has not been authorized by proper authority. Other practices which are specifically forbidden are:

1. Violation of radio silence.

10593

10235

2. Unofficial conversation between operators.

3. Transmitting in a direct net without permission.

4. Excessive tuning and testing.

5. Transmission of an operator's name or personal sign by other than the operator concerned.

6. Unauthorized use of plain language.

7. Use of unauthorized prowords.

8. Linkage or compromise of classified call signs and address groups by plain language disclosures or associated with unclassified call signs.

Other than the forbidden transmission, there are some things that should be avoided as much as possible. They are as follows:

1. Use of excessive power.

2. Needless loss of time in tuning, changing frequency, or adjusting equipment.

3. Transmission beyond the capabilities of receiving operators.

Authentication

Authentication is a security measure used to protect naval communication from fraudulent transmission. The best defense against imitative deception by the enemy is proper authentication. An authenticator is a letter, numeral, or groups of letters or numerals inserted in a message to prove its authentication. By correct use the operator can distinguish between genuine and fraudulent stations or transmissions.

Authentication is used, especially during wartime, when transmitting or receiving operating instructions may affect the military situation; examples include closing down a station, shifting frequency, or directing establishment of a special guard. Always authenticate when establishing radio contact with a station in an area where unfriendly forces are known to have communications interception capability. In this case, authenticators should be exchanged to prevent an enemy station from issuing false instructions to an unsuspecting station which would possibly produce a military situation favorable to the enemy.

Whenever an authentication system is promulgated, there will be accompanying instructions specifying how and when it is to be used; this is classified information.

EMERGENCY COMMUNICATIONS

Because of the infinite variety of possible situations, specific procedures cannot always be prescribed for every situation which might be considered an emergency. As a rule of thumb, an emergency includes any situation which places an aircraft in danger; i.e., uncertainty, alert, being lost, or in distress. Emergency communications would be any communications associated with these situations as described.

All military towers and most civil towers guard the emergency frequencies 121.5 MHz and 243.0 MHz. The prowords established for use to indicate the severity of an emergency situation in voice communication are MAYDAY, to indicate that the aircraft is threatened by serious and imminent danger and immediate assistance is required; and PAN, to indicate that the aircraft is in a situation which requires urgent action but is not in actual distress.

Controllers may expect to receive the following information from pilots of aircraft in an emergency condition:

1. PAN or MAYDAY 3 times and aircraft call sign 3 times.
2. Type of aircraft.
3. Actual or estimated position.
4. Heading.
5. Indicated airspeed.
6. Altitude/FL.
7. Fuel remaining.
8. Nature of emergency.
9. Pilot's intentions.
10. Assistance desired.
11. Two 10-second dashes with the mike button for DF purposes.

The pilot will accept "communications control" of one particular ground station, and all other stations must remain silent so as not to interfere.

CIRVIS Messages

The contraction CIRVIS is derived from the title of a document published by the Joint Chiefs of Staff, Joint Communication Electronics Board. It is entitled "Communications Instructions for Reporting Vital Intelligence Sightings from Airborne and Waterborne Sources." FAA facilities become involved with CIRVIS messages since they contact aircraft, both civil and military by radio.

The procedures used by aircraft to call ground stations and report CIRVIS information should be similar to those used when sending position reports, except that the call should be preceded by the word CIRVIS (pronounced SUR

10594

VEES) spoken three times to clear the frequencies of all other communications except DISTRESS or URGENCY. Should this procedure fail to clear the frequencies, the International Urgency Signal XXX transmitted three times on telegraph transmissions or the word PAN spoken three times may be employed as an alternate signal. CIRVIS reports are transmitted in plain language and as soon as possible (FLASH precedence is authorized) to any U.S. or Canadian military or civil air-ground communications facility.

There are three types of CIRVIS messages which controllers may be called upon to handle, as follows:

1. CIRVIS Report. Initial sighting report.

2. Additional CIRVIS reports. Additional reports should be made if more information becomes available concerning a previously sighted object. These reports should contain a reference to the original report to identify them with it.

3. Cancellation report. Cancellation reports should be made in the event that a previously reported sighting is positively identified as friendly or that it has been erroneously reported.

EXAMPLE OF INITIAL CIRVIS REPORT:

Aircraft—CIRVIS CIRVIS CIRVIS, KINDLEY THIS IS NAVY TWO FIVE NINER THREE SIX, CIRVIS REPORT, OVER.

Communications facility—NAVY TWO FIVE NINER THREE SIX, THIS IS KINDLEY, GO AHEAD.

Aircraft—NAVY TWO FIVE NINER THREE SIX SIGHTED FORMATION OF SIX JET BOMBERS, CONFIGURATION IS SWEPT WING WITH EIGHT JET ENGINES, TWO HUNDRED MILES EAST OF BERMUDA OR THIRTEEN MAY AT ONE THREE FIVE ZERO ZULU, ALTITUDE THREE FIVE THOUSAND, HEADING TWO SEVEN ZERO DEGREES, NO MARKINGS OBSERVED, OVER.

Communications station—KINDLEY, ROGER OUT.

FAA stations and Navy towers must immediately pass the CIRVIS message to the appropriate ARTCC. FAA ARTCC's in the conterminous United States forwards the CIRVIS message immediately by direct interphone to the appropriate Air Division Control center. If no direct interphone is available, the report should be relayed to the ARTC center nearest to and having direct interphone connection with the Air Division Control center. The Air Division is responsible for forwarding to other military services, or higher headquarters, as required.

TECHNIQUES

Proper microphone technique is important in radiotelephone communications. Transmissions should be concise and in a normal conversational tone. Consider the following suggestions for proper technique: Speak clearly and distinctly; avoid extremes of voice pitch; be natural; use standard phraseologies to the maximum extent practicable, but do not be afraid to use plain language where no precedence has been set; shield your mike from outside noises; keep your mike a sufficient distance from an associated speaker to avoid acoustical feedback; give an accurate response to a request for a radio check (a transmission with a high level of background noise is not LOUD AND CLEAR); do not depress the mike button until absolutely ready to talk; and do not tie up a frequency with excessive test signals and radio checks.

PHRASEOLOGY

The use of standard phraseology is necessary for efficient utilization of communications frequencies. Controllers through acquired experience in using standard phraseology are able to make transmissions as brief as possible yet completely understandable. Proficiency may be developed to the extent that in the exchange of communications between controller and pilot the intent of the message is comprehensible even before the verbal transmission is complete. In other words, proper phraseology is second nature to a proficient controller.

Identification of Ground Facilities

The Air Controlman must know how ground facilities such as towers, centers, approach control, and communications stations, are identified during radiotelephone communications. Then, he must know how to identify all types of aircraft, even those of foreign registry. He cannot communicate with these aircraft properly if he is not completely familiar with how to make radio contacts through use of standard phraseologies.

Airport traffic control towers are identified during radiotelephone communications as follows:

State the name of the facility, followed by the word "tower." Where military and civil airports are located in the same general area and have similar names, state the name of the military service, followed by the name of the military facility and the word "tower."

EXAMPLES: MEMPHIS TOWER; NAVY MEMPHIS TOWER.

Air Route Traffic Control Centers (ARTCC's) are identified by the location name followed by the word "center."

EXAMPLE: KANSAS CITY CENTER.

Approach control facilities, including Army radar approach control facilities (ARAC's), radar approach control facilities associated with the USAF (RAPCON's), and radar air traffic control centers associated with the USN (RATCC's), are identified by the name of the facility, followed by the words "approach control." Where military and civil facilities are located in the same general area and have similar names, state the name of the military service, followed by the name of the military facility, and the words "approach control."

EXAMPLES: DENVER APPROACH CONTROL; NAVY JACKSONVILLE APPROACH CONTROL.

Functions within a terminal facility are identified by the name of the facility, followed by the name of the function.

EXAMPLES: OCEANA DEPARTURE CONTROL; MERIDIAN GROUND CONTROL.

Radar facilities having air surveillance radar (ASR) and/or precision approach radar (PAR) but not providing approach control service are identified by the name of the facility followed by the letters "G-C-A."

EXAMPLE: OLATHE G-C-A.

Air traffic communications stations are identified during radiotelephone communications in the following manner:

Navy communications stations; by the word "Navy," followed by the name of the station and the word "radio."

EXAMPLE: NAVY NORFOLK RADIO.

Air Force communications stations; by the name of the station followed by the word "airways."

EXAMPLE: BROOKLEY AIRWAYS.

FAA flight service stations (FSS) by the name of the station followed by the word "radio."

EXAMPLE: LEXINGTON RADIO.

Aircraft Identification

Military aircraft are identified by one of the following:

1. The service name followed by the last five digits of the serial number.

EXAMPLE: NAVY FIVE SIX ONE TWO THREE.

2. Air evacuation flights, rescue flights, or helicopters, by the abbreviation AIR EVAC, RESCUE, or (service name) COPTER, as appropriate, followed by the last five digits of the serial number. The word COPTER may be omitted in transmissions subsequent to initial contact.

EXAMPLES: AIR EVAC ONE SEVEN THREE TWO ONE; RESCUE FIVE ONE SIX EIGHT FOUR; or, NAVY COPTER THREE TWO ONE ONE FIVE.

3. The abbreviations for special military operations followed by the last five digits of the serial number.

EXAMPLES: MAC SEVEN EIGHT FIVE SIX TWO (Military Airlift Command); SAM NINER ONE FIVE SIX TWO (Special Air Mission); LOGAIR SEVEN FIVE EIGHT SIX ONE (USAF Contract Aircraft).

4. Pronounceable words 3, 4, 5, and 6 letters followed by a 4-, 3-, 2-, or 1-digit number.

EXAMPLE: PAUL TWO ZERO.

5. An assigned double letter 2-digit flight number.

EXAMPLE: ALFA KILO ONE FIVE.

6. Navy and Marine fleet and training command aircraft, one of the following:

a. The service name and two letters (use phonetic alphabet equivalents), followed by two or three digits.

EXAMPLE: NAVY GOLF ALPHA TWO ONE.

b. The service name and a digit and a letter (use phonetic alphabet equivalents), followed by two or three digits.

EXAMPLE: MARINE FOUR CHARLIE TWO THREE SIX.

Civil aircraft are identified by the aircraft type, model name, or manufacturer's name (if none of these are known, use the word November or the letter N followed by the digits and letters of the registration number.

EXAMPLE: APACHE ONE FOUR TWO PAPA; DOUGLAS THREE ZERO ONE ROMEO; NOVEMBER THREE SEVEN ONE FIVE.

Air carrier and other civil aircraft having FAA authorized call signs are identified by the

call sign followed by the flight number in group form.

EXAMPLE: AMERICAN FIVE TWENTY ONE; COMMUTER SIX ELEVEN; GENERAL MOTORS THIRTY SEVEN.

Aircraft of foreign registry are identified by one of the following:

1. Civil—the letters or digits of the aircraft registration or call sign.
EXAMPLE: C-F-R-L-G.
2. Air carrier—the abbreviated name of the operating company followed by the letters or numbers of the registration or call sign or the flight number in group form.
EXAMPLES: AIR FRANCE F-L-R-L-G; SCANDINAVIAN SIXTY ONE.
3. Military—the name of the country and the military service followed by the separate digits or letters of the registration or call sign. An exception to this is Canadian military aircraft which are identified by the word CANFORCE, followed by the separate digits of the serial number.

EXAMPLES: BRAZILIAN AIR FORCE FIVE ONE SIX ONE TWO; or, CANFORCE FIVE SIX TWO SEVEN ONE.

Presidential or Vice Presidential aircraft are identified as follows:

1. When the President or the Vice President is aboard a military aircraft, state the name of the military service followed by the word ONE for the President or the word TWO for the Vice President.
2. When the President or the Vice President is aboard a civil aircraft, state the words EXECUTIVE ONE for the President or EXECUTIVE TWO for the Vice President.
3. When a member of the President's or Vice President's family is aboard any aircraft, if the U.S. Secret Service or the White House Staff determines it is necessary, state the words EXECUTIVE ONE FOXTROT for the President's family or EXECUTIVE TWO FOXTROT for the Vice President's family.

Presidential or Vice Presidential escort aircraft are identified by the word QUAIL followed by not more than two digits.

If a controller should encounter an unfamiliar call sign, the same identification as the pilot used in the initial callup should be used in the reply even though it may be different than those listed in the appropriate publications.

Procedure Words and Phrases

There are certain procedure words and phrases that have special meanings. These must be mastered by all Air Controlmen, as they are used repeatedly. The following are some of these procedure words and phrases and their meanings:

WORDS AND PHRASES	MEANING
Acknowledge	Let me know that you have received and understand this message.
Affirmative	Yes.
Correction	An error has been made in this transmission (or message indicated). The correct version is . . . .
Go ahead	Proceed with your message.
How do you head me	Self-explanatory.
I say again	Self-explanatory.
Negative	That is not correct.
Out	This conversation is ended and no reply is expected.
Over	My transmission is ended and I expect a reply from you.
Read back	Repeat all of this message back to me.
Roger	I have received all of your last transmission. (To acknowledge receipt; shall not be used for any other purpose.)
Say again	Self-explanatory.
Speak slower	Self-explanatory.
Standby	If used by itself means, I must pause for a few seconds. If the pause is longer than a few seconds, or if the word Standby is used to prevent another station from transmitting, it must be followed by the ending, OUT.
That is correct	Self-explanatory.
Verify	Check with originator.

10597 10598

WORDS AND PHRASES	MEANING
Wilco	I have received your message, understand it and will comply (for use by USN only).
Words twice	Communication is difficult. Please say every phrase twice. (As a request.) Since communication is difficult, every phrase in this transmission will be spoken twice. (As information.)

Statement of Numbers

Statement of numbers is always of extreme importance in radiotelephone messages. The following pronunciation of the numerals has been found to be the best and most intelligible.

NUMERALS	PRONUNCIATION
1	WUN
2	TOO
3	TREE
4	FOW-ER
5	FIFE
6	SIX
7	SEV-EN
8	AIT
9	NIN-ER
0	ZERO

ALTITUDES.—State the separate digits of the thousands plus the hundreds.

EXAMPLES:

ALTITUDE	STATEMENT
500	FIVE HUNDRED
4,500	FOUR THOUSAND FIVE HUNDRED
9,000	NINER THOUSAND
10,000	ONE ZERO THOUSAND
13,000	ONE THREE THOUSAND

FLIGHT LEVELS.—State the words FLIGHT LEVEL, followed by the separate digits of the flight level.

EXAMPLES:

FLIGHT LEVELS	STATEMENT
180	Flight level one eight zero.
275	Flight level two seven five.

SERIAL NUMBERS.—State the separate digits.

EXAMPLES:

NUMBER	STATEMENT
18143	ONE EIGHT ONE FOUR THREE
26075	TWO SIX ZERO SEVEN FIVE

TIME.—State the separate digits of the hour and minutes in terms of Greenwich Mean Time (GMT) based on the 24-hour clock.

EXAMPLES:

TIME	STATEMENT
0615 GMT	ZERO SIX ONE FIVE
2230 GMT	TWO TWO THREE ZERO

NOTE: GMT is often referred to as ZULU time which is the phonetic equivalent of the designated letter suffix (Z) of the zero time zone.

Upon request, state the digits of the hours and minutes in terms of GMT, followed by local standard time based on the 24-hour clock.

EXAMPLE:

TIME	STATEMENT
1430 PST (2230 GMT)	TWO TWO THREE ZERO GREENWICH, ONE FOUR THREE ZERO PACIFIC.

TIME CHECKS.—State the word TIME followed by the separate digits of the hour, minutes, and nearest quarter minute.

EXAMPLE: TIME, ONE FOUR ONE FIVE AND THREE QUARTERS.

ABBREVIATED TIME.—State the separate digits of the minutes only.

EXAMPLE:

TIME	STATEMENT
1415	ONE FIVE

10598

10598

POWER OUTPUT

The ability of the transmitter to provide sufficient power is also a limiting factor. Increasing the PRF increases the average power a proportional amount as shown by the equation

Average Power = Peak Power x Pulse Width x PRF

The useful power of the transmitter is that contained in the pulses and is termed the peak power of the system. Power is normally measured as an average value over a relatively long period of time. Since the radar transmitter is resting for a time which is long with respect to its operating time, the average power delivered during one cycle of operation is extremely low compared to the peak power available during the pulse time. High peak power is desirable to produce a strong echo at the maximum range of the equipment. Low average power enables the transmitter tubes and circuit components to remain cooler while operating and thus can be made smaller and more compact.

SCAN RATE AND BEAM WIDTH

Another factor affecting the PRF is the rate of angular motion of the antenna in searching extensive regions. If the antenna is moved through too large an angle between pulses, not only will the number of pulses per target be too low, but there may even be areas in which targets may exist without their being detected. In this connection, still another factor to consider is the sharpness of the antenna beam. A sharp beam must be pulsed more often than a wide beam to avoid skipping over targets.

The following equation shows the relationship of the antenna beam width, PRF, and antenna scan rate:

$$N_B = \frac{\theta_B f_r}{\dot{\theta}_s}$$

where

θ_B = antenna beam width in degrees

f_r = PRF in pps

$\dot{\theta}_s$ = antenna scanning rate in deg/sec

N_B = the number of pulses returned from a point target as the antenna scans through its beam width. (Generally, at least 10 pulses must be returned from a point target for reliable detection probability.)

RECEIVER SENSITIVITY

The sensitivity of radar is determined by several factors. Among these are transmitter output, transmitter frequency spectrum, pulse width, losses in the RF line, signal losses in the TR and ATR boxes, and receiver design and operation.

The sensitivity of a radar receiver is its ability to respond to weak echoes; the more sensitive the receiver, the greater the detection range of the radar.

The sensitivity of a radar receiver does not depend on the maximum amount of gain obtainable but on the noise level of the receiver. In other words, the gain could be increased many times above a given figure, but receiver noise would be amplified so greatly that a weak signal could not be seen among the "grass" and "clutter" produced on the indicator scope by the noise. Thus, the noise level of a receiver places a limit on the sensitivity of the receiver. The noise level depends on several factors. The signal-to-noise ratio in the first receiver stage is most important. Increasing the gain increases the noise level as well as the signal level. Receiver gain, therefore, is the result of a compromise between signal amplification and noise amplification.

Though noise voltages are highly undesirable in radar receivers, they cannot be completely avoided due to circuit elements. Although receivers have been built having greater input sensitivity, their operating limit is determined by the noise level within the receiver. When the signal voltage level falls below the noise voltage level, the returning signals are obscured by noise on the indicator. A further increase in amplification is useless because the noise and signal voltages are both amplified equally. Therefore, the highest obtainable signal-to-noise ratio is desired in the input stage of a radar receiver in order that the signal at the indicator is discernible from the noise. The loss of small power in the echo

FIELD ELEVATION.—State the words FIELD ELEVATION followed by the separate digits of the elevation.

EXAMPLES:

ELEVATION	STATEMENT
17 feet	FIELD ELEVATION ONE SEVEN
150 feet	FIELD ELEVATION ONE FIVE ZERO

ALTIMETER SETTING.—State the word ALTIMETER, followed by the separate digits of the altimeter setting.

EXAMPLE:

SETTING	STATEMENT
30.01	ALTIMETER, THREE ZERO ZERO ONE

SURFACE WIND.—State the word WIND, followed by the indicated wind direction to the nearest 10-degree heading, the words DEGREES AT, and the indicated velocity in knots.

EXAMPLE:

WIND, TWO SIX ZERO DEGREES AT ONE FIVE.

HEADINGS.—State the word HEADING, followed by the three digits of the number of degrees and omit the word DEGREES. Use heading 360 to indicate a north heading.

EXAMPLES:

HEADING	STATEMENT
005 degrees	HEADING ZERO ZERO FIVE
095 degrees	HEADING ZERO NINER FIVE

RADAR BEACON CODES.—State each digit of the four-digit code.

EXAMPLES:

CODE	STATEMENT
1000	ONE ZERO ZERO ZERO
2100	TWO ONE ZERO ZERO

RUNWAYS.—State the word RUNWAY, followed by the separate digits of the runway designation. For a parallel runway, state the word LEFT, CENTER, or RIGHT if the letter L, C, or R is included in the designation.

EXAMPLES:

DESIGNATION	STATEMENT
3	RUNWAY THREE
24L	RUNWAY TWO FOUR LEFT
7R	RUNWAY SEVEN RIGHT

FREQUENCIES.—State all the digits of the frequency, inserting the word POINT where the decimal point occurs. When the frequency is in the LF/MF band, include the word KILOHERTZ.

EXAMPLES:

FREQUENCY	STATEMENT
142.74 MHz	ONE FOUR TWO POINT SEVEN FOUR
360.2 MHz	THREE SIX ZERO POINT TWO
302 kHz	THREE ZERO TWO KILOHERTZ

SPEEDS.—State the separate digits of the speed followed by the word KNOTS.

EXAMPLES:

SPEED	STATEMENT
250	TWO FIVE ZERO KNOTS.
180	ONE EIGHT ZERO KNOTS.
90	NINER ZERO KNOTS.

International Phonetic Alphabet

It is quite often necessary to identify particular letters and groups of letters and/or spell out difficult words since certain sounds have low intelligibility when heard in noise. The standard phonetic alphabet identifies each letter of the alphabet with more readily recognized words. This is done to make the message clear when individual letters of the alphabet are transmitted, and to spell out words that are hard to understand on the air. The phonetic alphabet is as follows:

LETTER	RECOGNIZED WORD	PRONUNCIATION
A	ALFA	AL-FAH
B	BRAVO	BRAH-VOH
C	CHARLIE	CHAR-LEE or SHAR-LEE
D	DELTA	DELL-TAH
E	ECHO	ECK-OH
F	FOXTROT	FOKS-TROT

10599

10598

LETTER	RECOGNIZED WORD	PRONUNCIATION
G	GOLF	GOLF
H	HOTEL	HOH-TELL
I	INDIA	IN-DEE-AH
J	JULIETT	JEW-LEE-ETT
K	KILO	KEY-LOH
L	LIMA	LEE-MAH
M	MIKE	MIKE
N	NOVEMBER	NO-VEM-BER
O	OSCAR	OSS-CAH
P	PAPA	PAH-PAH
Q	QUEBEC	KEH-BECK
R	ROMEO	ROW-ME-OH
S	SIERRA	SEE-AIR-RAH
T	TANGO	TANG-GO
U	UNIFORM	YOU-NEE-FORM or OO-NEE-FORM
V	VICTOR	VIK-TAH
W	WHISKEY	WISS-KEY
X	XRAY	ECKS-RAY
Y	YANKEE	YANG-KEY
Z	ZULU	ZOO-LOO

Routes and Navaids

Air controlmen operating at the Ground Control position in the control tower will be required to relay IFR clearances to IFR flights. A careful study of the following procedures and examples will enable him to properly describe routes and navaids, using proper phraseology.

VOR/VORTAC/TACAN AIRWAYS.—State the word VICTOR followed by the number of the airway in group form.

EXAMPLE: VICTOR THREE NINETEEN.

VOR/VORTAC/TACAN JET ROUTES.—State the letter J followed by the route number in group form.

EXAMPLE: J SIXTY NINER.

L/MF AIRWAYS.—State the color of the airway followed by the number in group form.

EXAMPLE: BLUE EIGHTY ONE.

VOR/VORTAC/TACAN RADIAL.—State the name of the navaid, followed by the magnetic bearing of the radial, omitting the word DEGREE.

EXAMPLE: MEMPHIS TWO FIVE ZERO RADIAL.

ARCS ABOUT VOR-DME/VORTAC/TACAN NAVAIDS.—State the distance in miles from the navaid, followed by the words MILE ARC, the direction from the navaid in terms of the eight principal points of the compass, the word OF, and the name of the navaid.

EXAMPLE: TWO ZERO MILE ARC NORTHWEST OF EL CENTRO TACAN.

L/MF RANGE COURSES.—State the name of the station, followed by the bearing of the course from the station in terms of the eight principal points of the compass, and the word COURSE.

EXAMPLE: ROSWELL NORTHEAST COURSE.

NONDIRECTIONAL BEACON COURSES AND BEARINGS.—State the course to, or the bearing from the radio beacon, omitting the word DEGREE, followed by the words MAGNETIC COURSE TO, or MAGNETIC BEARING FROM, the name of the radio beacon and the words RADIO BEACON.

EXAMPLES: ZERO FOUR FIVE MAGNETIC BEARING FROM MEMPHIS RADIO BEACON; TWO TWO FIVE MAGNETIC COURSE TO MEMPHIS RADIO BEACON.

VOR-DME/VORTAC/TACAN FIXES.—When the fix is not named, state distance in miles, followed by the phrase MILE D-M-E FIX, and the specified radial.

EXAMPLE: ONE TWO MILE D-M-E FIX, ARGENTIA TWO FOUR ZERO RADIAL.

When the fix is named, state the name of the fix followed by the phrase D-M-E FIX.

EXAMPLE: EAST GATE D-M-E FIX

Radio Contact Procedure

Radio communications may be initiated with an aircraft by using the following format:

1. Initial callup:
   a. Identification of the aircraft being called.
   b. The words THIS IS.
   c. Identification of the calling unit.
   d. The type of message to follow, when this will assist the pilot.
   e. The word OVER.
2. Replying to callup from an aircraft:
   a. Identification of the aircraft initiating the callup.
   b. The words THIS IS.
   c. Identification of the replying unit.
   d. The word OVER.

EXAMPLES: MARINE THREE ONE FIVE SIX EIGHT, THIS IS LEMOORE TOWER, ATC CLEARANCE, OVER; NAVY GOLF ALFA TWO ONE, THIS IS LEMOORE TOWER, OVER.

This same format is used after communication has been established except that after

stating the identification of the calling or replying unit, the message to be sent is stated or the message received is acknowledged.

A clearance or instructions intended for a specific aircraft must be prefaced with the identification of that aircraft, except that aircraft identification may be omitted after initial callup when conducting the final descent portion of a radar approach.

Where no confusion is likely, transmissions may be shortened as follows:

1. After communications have been established, the aircraft identification (with the exception of an air carrier or other civil aircraft having an FAA authorized call sign) may be shortened to the appropriate prefix and the last 3 digits or letters of the identification number, and the facility identification may be omitted.

2. The words THIS IS may be omitted and the word OVER may be omitted when the message obviously requires a reply.

3. A message may be transmitted immediately after callup (without waiting for aircraft reply) when it is short and receipt is generally assured.

In the following example, the words which may be omitted are enclosed within parentheses:

Aircraft - MIRAMAR TOWER (THIS IS) NAVY SEVEN FIVE ONE THREE ONE, OVER.

Tower - NAVY SEVEN FIVE ONE THREE ONE, (THIS IS) MIRAMAR TOWER, (OVER).

Aircraft - (MIRAMAR TOWER) (THIS IS) NAVY (SEVEN FIVE) ONE THREE ONE, FOUR MILES SOUTH (AT) TWO THOUSAND, LANDING MIRAMAR, (OVER).

Traffic Clearances And Instructions

An airport traffic controller should issue such traffic clearances and instructions as are, in his judgment, necessary for the purpose of controlling and protecting air traffic. He accomplishes this by aiding pilots in the prevention of collisions between aircraft under his jurisdiction.

A clearance issued by an airport traffic control tower is authority for a pilot to proceed only insofar as known air traffic and field conditions are concerned; it does not constitute authority for him to violate any provisions of military or federal air regulations.

Clearances issued by airport traffic controllers are predicated upon known or observed traffic and field conditions which, in the judgment of the controller, affect safety in aircraft operations. Such known traffic conditions include not only aircraft observed in the air within the control zone and on the movement area over which control is being exercised, but also any known or observed vehicular traffic or other obstructions not permanently installed on the movement area in use.

If a clearance issued by the airport traffic controller is not acceptable to the pilot, he may request and, if practicable, receive an alternate clearance.

Departure Information

The following information, as appropriate, is issued to departing aircraft:

1. Runway in use.

EXAMPLE: TAXI TO RUNWAY TWO FOUR LEFT; or, RUNWAY TWO FOUR LEFT.

2. Surface wind.

3. Altimeter setting. Unless specifically requested by the pilot, this need not be issued to local aircraft operators who have requested this omission in writing or to scheduled air carriers.

4. Time check to all USN/USAF IFR traffic and when requested by VFR traffic.

5. Issue the official ceiling and visibility to a departing aircraft before takeoff as follows:

a. To a VFR aircraft—when weather is below VFR minima.

b. To an IFR aircraft—when weather is below that published as the highest takeoff minimums for the airport, or if none are published, when weather is below VFR minimums.

6. Taxi information as necessary. Taxi route information need not be issued unless specifically requested by the pilot.

7. Inform departing IFR aircraft of the appropriate departure control frequency. This may be issued on the clearance delivery frequency or ground control frequency as applicable.

The following is an example of departure information issued in response to a request for such from the pilot of a departing IFR aircraft:

NAVY ONE THREE SEVEN, MAYPORT GROUND CONTROL, RUNWAY TWO FOUR LEFT, WIND TWO ONE ZERO DEGREES AT

ONE FIVE, ALTIMETER THREE ZERO ZERO ONE, TIME ONE FOUR ONE FIVE AND ONE QUARTER, TAXI EAST ON THE PARALLEL TAXIWAY, DEPARTURE CONTROL FREQUENCY WILL BE THREE TWO FIVE POINT TWO.

Normally, the taxi instructions issued permit an aircraft to proceed to a specified point without delay or confliction to other traffic under tower jurisdiction. If in the judgment of the controller, a potential conflict exists, taxiing aircraft must be held short of the area in which the conflict may exist to await further instructions. Issue concise and easily understood taxi information.

An EXAMPLE of taxi instructions from one point to another on the movement area would be as follows:

NAVY TWO ONE SEVEN TURN RIGHT AT THE FIRST INTERSECTION, TAXI ON THE PARALLEL TAXIWAY, HOLD SHORT OF RUNWAY TWO FOUR.

Subsequent taxi instructions to the above would be as follows:

NAVY TWO ONE SEVEN CLEARED TO CROSS RUNWAY TWO FOUR, CONTINUE TAXIING STRAIGHT AHEAD. TURN LEFT AT THE NEXT INTERSECTION TO OPERATIONS.

The absence of holding instructions authorizes the aircraft to cross all runways which the taxi route intersects except the runway to which it has been instructed to proceed.

TAKEOFF CLEARANCE

The takeoff clearance, as the name implies, is issued after the aircraft has taxied to the warmup area at the end of the runway. The pilot has previously received information on the runway in use, wind direction and velocity, the altimeter setting, and time check. By his statement to the tower, READY FOR TAKEOFF, the pilot indicates he is interested in obtaining authorization to commence his takeoff, and he needs information on such local traffic that may affect his flight while in the control zone.

Takeoff clearance should be issued in the following form:

1. (Identification).
2. (Any pertinent information).
3. CLEARED FOR TAKEOFF.

EXAMPLE: NAVY THREE TWO ONE, CLEARED FOR TAKEOFF.

Immediately after takeoff, many pilots want their time off the ground. An EXAMPLE of a response to such a request would be as follows:

NAVY ONE TWO THREE, OFF AT ONE SIX.

Aircraft may be authorized to taxi into takeoff position and hold when takeoff clearance cannot be issued because of traffic. Traffic information should be issued such aircraft unless the traffic is another aircraft which has landed or is taking off on the same runway.

EXAMPLE: TAXI INTO POSITION AND HOLD (traffic information, if required).

Aircraft CANNOT be authorized to taxi into position to hold for an unreasonable length of time before takeoff clearance can be issued or to hold simultaneously on intersecting runways.

When issuing additional instructions or information to an aircraft holding in takeoff position, include instructions to continue holding or taxi off the runway, unless it can be cleared for takeoff.

EXAMPLE: CONTINUE HOLDING; or, TAXI OFF THE RUNWAY.

Clearance for a requested right/left turn after takeoff is given at the discretion of the controller based on the existing traffic situation, and is usually included with the takeoff clearance. This would be stated as:

RIGHT/LEFT TURN APPROVED, CLEARED FOR TAKEOFF.

In the event an aircraft is on final approach and there is still sufficient time to clear a departing aircraft for takeoff, the following phraseology should be used:

CLEARED FOR IMMEDIATE TAKEOFF.

In the event an aircraft is on final approach and there is still sufficient time to clear a departing traffic aircraft which is in takeoff position, but some doubt exists as to whether or not the departing aircraft will take off immediately, the following phraseology should be used:

TAKE OFF IMMEDIATELY OR TAXI OFF THE RUNWAY.

Intersection takeoffs may be authorized to expedite the movement of traffic. Such procedure may be initiated by a controller or in response to a pilot's request. If a pilot requests the distance from the intersection to the end of the runway, the measured distance from an appropriate chart constructed for this purpose is issued.

Landing Information and Instructions

Instructions to enter the traffic pattern to approach the airport and land must include the following:

1. Specific traffic pattern information. (May be omitted if the aircraft is to circle the airport to the left.)

EXAMPLES:

ENTER LEFT/RIGHT BASE.
STRAIGHT-IN.
MAKE STRAIGHT-IN.
STRAIGHT-IN APPROVED.
RIGHT TRAFFIC.
MAKE RIGHT TRAFFIC.
RIGHT TRAFFIC APPROVED.
CONTINUE.

2. Runway in use.
3. Surface wind direction and velocity. (When the aircraft is being controlled by a radar facility not having wind measurement equipment, relay this information to the radar controller at the time approach, landing, or touch-and-go clearance is issued.)
4. Any supplementary information.
5. Clearance to land (when appropriate).
6. Requests for additional position reports when required.

Using the above form, instructions governing a flight from a visual reporting point, holding point or fix, or other outlying point to the traffic pattern would be stated as follows:

NAVY THREE TWO NINER, THIS IS NAVY MEMPHIS TOWER, ROSEMARK AT TWO THOUSAND, ENTER DOWNWIND, RUNWAY THREE SIX, WIND ZERO ONE ZERO DEGREES AT ONE FIVE, REPORT ENTERING DOWNWIND.

Instructions to a jet aircraft that will use the overhead type of approach would be as follows:

NAVY FOUR ONE FIVE, THIS IS OCEANA TOWER, FIVE MILES SOUTH AT TWO THOUSAND, RUNWAY THREE TWO LEFT, WIND THREE ONE ZERO DEGREES AT ONE FIVE, REPORT INITIAL.

The instructions to enter a traffic pattern should not be confused with the clearance to land since the former is issued when the aircraft is some distance from the field and traffic conditions usually do not permit the issuance of a landing clearance at that point.

Clearance to land should be given as follows:

NAVY THREE TWO NINER, CLEARED TO LAND.

In the event aircraft are landing and taking off at an airport without coming to a stop during their landing roll, such operations are described as touch-and-go landings. Pilots are required to request approval of same at least by the time they are turning on their final approach leg. Approval for such operation should be issued by use of the following phraseology:

CLEARED FOR TOUCH-AND-GO.

In the event it is not possible to approve a requested touch-and-go operation, but a full stop landing can be approved, the following phraseology is used:

UNABLE TOUCH-AND-GO, MAKE FULL STOP LANDING OR GO AROUND (CIRCLE THE FIELD).

If an aircraft cannot be cleared to land and it is desired that it continue to circle the airport, the following phraseology should be used:

CIRCLE THE AIRPORT.

When it is desired to delay an aircraft in effecting separation, and a normal circle of the field would take more than the required time, the following phraseology should be used if circumstances permit:

MAKE LEFT/RIGHT THREE SIXTY/TWO SEVENTY.

When an aircraft is on final approach and it becomes necessary to cancel the landing clearance, the following phraseology should be used:

GO AROUND.

Whenever it is desired that pilot shorten his approach path, the following phraseology should be used:

MAKE SHORT APPROACH.

When it is desired that the pilot lengthen the downwind leg, the following phraseology should be used:

EXTEND DOWNWIND.

To inform pilots of arriving aircraft of their respective positions in the traffic pattern landing sequence, the following phraseology may be used:

NUMBER (landing sequence number).

If it is desirable or necessary to be specific and indicate that an arrival follow a particular aircraft in the traffic pattern, the following phraseology may be used:

FOLLOW (description and location of traffic).

If other landing traffic is utilizing a runway different from that which an arriving aircraft will use, traffic information should be issued to the arrival as follows:

TRAFFIC IS (description and location of traffic)

LANDING RUNWAY (number).

When describing location, descriptions such as TO YOUR RIGHT, ABOVE YOU, ONE MILE AHEAD OF YOU, etc., are much more satisfactory than NORTH OF YOU, ONE MILE EAST OF YOU, etc.

Request aircraft to report wheels down when it reaches an appropriate position in the traffic pattern, unless the pilot has previously reported wheels down, as follows:

REPORT WHEELS DOWN.

Landing clearance should not be issued to an arriving aircraft until a WHEELS DOWN report is received.

In the event an aircraft has encountered landing gear difficulty and has to proceed within close proximity of the control tower for personnel to observe the landing gear, the following phraseology should be used:

1. If the landing gear appears to be in a normal position the control tower personnel should transmit:

LANDING GEAR APPEARS DOWN AND IN PLACE.

2. If the landing gear does not appear normal, a description of the appearance should be given, as for example:

RIGHT WHEEL APPEARS RETRACTED, or LEFT WHEEL DOES NOT APPEAR IN PLACE.

Additional Phraseology

Controllers approve or disapprove pilots' requests as circumstances and traffic conditions permit. In cases where specific phraseology is not set forth for the applicable procedure, use of the words APPROVED, or UNABLE (include reason and/or additional instruction when necessary), as appropriate.

EXAMPLES: FREQUENCY CHANGE APPROVED; UNABLE HIGH SPEED LOW APPROACH, SLOWER TRAFFIC IN THE PATTERN.

The word IMMEDIATELY is used in phraseology only when expeditious compliance is required to avoid an imminent situation. If time permits, the reasons for this action should be included.

AC's should refer to the appropriate sections of TATC Handbook 7110.8 (Series) for additional phraseology not included here or for possible changes thereto.

FIGHTER DIRECTOR VOCABULARY

Air Controlmen should be well versed in the brevity codes which are used for aircraft control, search and rescue, carrier deck conditions, and flight operations. These brevity codes are provided in the current Allied Communications Publication (ACP) 165 and are required knowledge factors for all Air Controlmen.

DIRECTION FINDER COMMUNICATIONS PROCEDURES

Direction finder communication procedures may not always be identical, as situations may arise which necessitate modifications. Listed below is a typical D/F voice procedure:

1. Pilot calls D/F station:
NAVY MEMPHIS TOWER, THIS IS NAVY 34568, REQUEST STEER, OVER.
2. D/F station acknowledge callup:
NAVY 34568, THIS IS NAVY MEMPHIS TOWER. TRANSMIT FOR STEER, OVER.
3. Pilot replies:
NAVY MEMPHIS TOWER THIS IS NAVY 568 TRANSMITTING FOR STEER (pilot then depresses microphone button for a period of approximately 15 seconds).
4. D/F station replies:
NAVY 568, THIS IS NAVY MEMPHIS TOWER. STEER WITH ZERO WIND IS 180, OVER.
5. Pilot replies:
NAVY MEMPHIS TOWER, THIS IS NAVY 568, MY STEER IS 180, OUT.

Frequent followup checks are made, as outlined above (about every 30 seconds to 1 minute) to compensate for wind drift, compass error, etc., and to insure that the aircraft does not overfly the station. When the pilot states he no longer requires or desires this service, the D/F steer is then discontinued.

VISUAL COMMUNICATIONS

PORTABLE TRAFFIC CONTROL SIGNALS AND MEANING

The nomenclature and operation of the portable traffic control light were previously discussed in chapter 4. However, since the portable traffic control light is used to control the movement of personnel and vehicles on the landing area, as well as aircraft without radio, the control signals and their meaning are discussed at this time.

10604 40204

AC.131

Figure 10-1.—Portable traffic control light signals.

10605 10604

Table 10-1.--Meaning of traffic control light signals.

Color and type of signal	On the ground	In flight
STEADY GREEN	Cleared for takeoff	Cleared to land
FLASHING GREEN	Cleared to taxi	Return for landing (to be followed by steady green at proper time).
STEADY RED	Stop	Give way to other aircraft and continue circling.
FLASHING RED	Taxi clear of landing area (runway) in use.	Airport unsafe—do not land.
FLASHING WHITE	Return to starting point on airport.	Not applicable.
ALTERNATING RED AND GREEN	General warning signal—exercise extreme caution.	

In addition to the operation and limitations of the portable traffic light, the Air Controlman must know the meaning of the traffic control light signals used. Figure 10-1 shows the meaning of the signals to be used for aircraft, vehicles, and personnel on the ground and for aircraft in the air. This is shown in tabular form in table 10-1.

A series of alternating red and green flashes from a directed traffic control light are used as general warning signals to advise a pilot or driver of a vehicle on the landing area to be on the alert for hazardous or unusual conditions. As an example, the warning signal may be directed to a pilot to indicate a change of runway, since this can prove hazardous if the pilot attempts to land crosswind.

In controlling traffic by means of visual signals it should be remembered that the warning signal is not a prohibitive signal. This means that it may be followed by either a red or a green light as circumstances warrant. The general warning signal is directed to pilots of the aircraft concerned as follows:

1. When aircraft are converging and there is a possibility of collision.

2. When hazardous conditions are present and the pilot must be unusually alert in order to complete the operation safely. (Such conditions include obstructions, soft field, ice on runway, and many others.)

3. When mechanical trouble is apparent to the controller and he has reason to believe that the pilot may not be aware of it.

4. At any other time when believed necessary in the opinion of the controller.

SPECIAL LIGHT SIGNALS

Aircraft Inbound Without Radio

Between sunset and sunrise, a pilot wishing to land should turn on a landing light as he approaches the airport unless he has already been given a green light.

A series of flashes of a landing light by a pilot intending to land mean: If the floodlight is on, the pilot wants it turned off; and if the floodlight is off, the pilot wants it turned on.

Pilots should acknowledge portable traffic control light signals by rocking the aircraft's wings during hours of daylight and by blinking their landing or navigation lights during the hours of darkness.

Aircraft on the Airport Without Radio

During the hours of darkness, a pilot wishing to attract the attention of the control tower

10606

operator should turn on a landing light and taxi the aircraft in a position so that the light is visible to the tower controller. The landing light should remain on until appropriate signals are received from the tower.

Pilots should acknowledge light signals by moving the ailerons or rudder during the hours of daylight or by blinking the landing or navigation lights during the hours of darkness.

Low Ceiling and Visibility Signals

During the hours of daylight, the lighting of the airport rotating beacon (fig. 10-2) means that the ground visibility in the control zone is less than 3 miles and/or the ceiling is less than 1,000 feet. Flashing light outlining the traffic direction indicator at night (fig. 10-2) indicate that the ground visibility in the control zone is less than 3 miles and/or that the ceiling is less than 1,000 feet.

Airport Course Lights

Some military airports have special light signals, such as course lights, which indicate landing direction, runway in use, traffic pattern in use, and other similar information for local activities. These lights are to be used as directed by the commanding officer. The principal advantage in using the course lights is that it gives pilots pertinent and specific visual information; therefore, radio contact with the control tower is unnecessary. However, the meaning and arrangement of these lights have no standardization and are used only for pilots known to be familiar with the meaning of the special light signals.

VISUAL EMERGENCY SIGNALS

Visual emergency signals are the means by which downed airmen communicate with rescue aircraft. Airmen in distress should use every effort to attract attention either by means of radio or visual emergency signals. Visual emergency signals consist of various positions of the body and its extremities, the display panels, and parts of the aircraft itself which may be used if not destroyed. These parts consist of engine cowling, doors, flooring, ailerons, strips of fabric, etc., and, in addition, pyrotechnic light and smoke signals.

ROTATING BEACON (day only)

Ground visibility in control zone less than 3 miles and/or ceiling less than 1,000 feet. Traffic clearance required for landings, takeoffs, or flight in the traffic pattern in a control zone.

FLASHING LIGHTS
OUTLINING TRAFFIC DIRECTION INDICATOR (night only)

Ground visibility in control zone less than 3 miles and/or ceiling less than 1,000 feet. Traffic clearance required for landings, takeoffs, or flight in the traffic pattern in a control zone.

AC.132

Figure 10-2.—Light signals used in air traffic control.

Body Signals

The body signals as illustrated in figure 10-3 are used by airmen who have made forced landings to attract the attention of a rescue aircraft. Messages are transmitted to the pilot by using these body signals as the aircraft circles over the location of the downed airmen. The person using the body signals should stand in the open making certain the background, as seen from the air, is not confusing. Each motion must be accomplished slowly, and each signal repeated until the person being rescued is positive that the pilot understands the message.

Visual Panel Signals

The international ground-to-air emergency code for use in distress signals when using display panels is shown in figure 10-4. These signals are for international use by personnel who crash in aircraft or descend by parachute in remote areas and who are in need of medical assistance, food, or information as to what

AC.133

Figure 10-3.—Body signals.

route should be followed in order to effect rescue.

The symbols may be made by laying out strips of fabric or parachutes, pieces of wood, peeled logs, stones, or any available material. As much color contrast as possible should be provided between material being used for the symbols and the background against which the symbols are exposed. Ground contrast can be often increased by using fluorescein dye sea-marker to dye uncolored parachutes, snow, or light sand. The symbols should be at least 8 to 10 feet high. Care should be taken to lay out the symbols exactly as shown in figure 10-4 to avoid confusion with other panel display communication symbols. When the ground is covered with snow, signals can be made by dragging, shoveling, or tramping the snow, as the depressed areas forming the symbols should appear to be black from the air. In addition to

10608 60001

signal or the addition of an equally small noise power in the input stage may reduce the maximum range of the radar set as much as the loss of large amounts of power from the transmitter. Thus, the sensitivity of a radar receiver is measured by the smallest input signal that can produce an output signal discernible against the noise background on the indicator.

In order to obtain as high a signal-to-noise ratio as possible a compromise must be made. If the band-pass of the IF amplifiers is increased, the pulse shape will be maintained as desired but the noise, which is random frequencies, will also be amplified.

If the band-pass of the IF amplifier is decreased, the random frequency noise will be decreased but the pulse shape will be distorted. (This distortion is due to the composition of the square pulse desired which contains many harmonics.)

RF amplifiers are normally not used due to their high noise level when operating in the microwave region. This noise level is due to thermal agitation, shot noise, and induced grid noise. A remedy for noise created in microwave amplifiers is the traveling wave tube, discussed in chapter 9 of Basic Electronics. This tube is fleet use.

The compromise, therefore, is the allowable distortion of the echo pulse versus the acceptable noise level.

BASIC RADAR SYSTEM

Radar sets currently used in aviation vary greatly in detail and in the function they are designed to accomplish. They may be very simple or, if more accurate data is required, they may be highly refined. However, the principles of operation are essentially the same for all sets. Thus, a single basic radar set can be visualized in which the functional requirements hold equally well for all specific sets. The varying details are due to a choice of specific circuits to fulfill these general functional requirements. In general the degree of refinement of radar circuits increases as the operating frequency of the radar increases. (Microwave frequencies lend themselves to a higher degree of precision in determining angular measurement.)

A typical pulse radar set consists essentially of six basic components—synchronizer (timer), transmitter, antenna system, receiver, indicator, and power supply. The relationship of each component is illustrated by block diagram in figure 15-2 (A).

SYNCHRONIZER

The circuits in an airborne radar system that control or synchronize the operation of the various componenets of the system are known as timing circuits.

The functions which the timing circuits must perform depend to a large extent upon the purpose of the set, the type of modulator used, and the method of data presentation employed. Thus, the functional block diagram shown in figure 15-2 (A) does not apply to any particular set but shows a method of control (timing) which is used in airborne radar sets.

Figure 15-2 (B) shows the control pulses furnished by the timer and their proper time relationships to the transmitted pulse.

The first pulse (waveform (1), fig. 15-2(B)) is the transmitter trigger. It causes a pulse of RF energy to be transmitted as shown in waveform (2). The transmitter trigger also acts as a reference point from which the other operations are timed.

The timer also supplies a trigger pulse to start the range sweep as shown in waveform (3). However, in some radar sets both the transmitter trigger and the range sweep trigger are delayed. The transmitter trigger delay is a fixed amount, and the range sweep delay may be varied to allow the start of the range sweep as desired. This enables the range sweep trigger to start the sweep at exactly the same time as the transmitter fires, regardless of any inherent delay in the sweep circuit. This time is usually referred to as time zero (t_0), shown as the dotted line in figure 15-2 (B).

Another voltage which the timer may supply in an intensifier pulse, waveform (4), usually referred to as an intensity gate. The intensity gate functions to blank the indicator except during the time of the desired range sweep. Thus, signals arriving outside the time interval corresponding to the desired range are eliminated. The intensity gate shown in waveform (4) is applied to the grid of the CRT. This gate cancels the CRT's disabling voltage, thus allowing the video signal to intensity-modulate the electron stream. An alternate method is to make the CRT normally operative and to apply a negative gate, or blanking pulse, to

1058

AC.134

Figure 10-4.—Ground-to-air emergency code.

ground (or surface vessel), or from ground (or surface vessel) to aircraft. The signals are used for either day or night identification and communication. The pyrotechnic pistol and signals are not described because the Air Controlman likely will have little contact with them. Instead, he will need to know the use made of using symbols, every effort is to be made to attract attention by means of radio, flares, smoke, or other available means.

Pyrotechnic Light and Smoke Signals

Aircraft signals are intended to be fired from aircraft to aircraft, from aircraft to signals locally and be able to recognize the signals when fired.

Use of aircraft signals are many and varied. Various color combinations are carried and used. They may be used by pilots when forced down or during emergencies. The Air Controlman often sees them used at air stations, particularly during night-flying operations. It is common practice for a runway watch to be stationed near the end of the duty runway. Whenever a landing aircraft appears to have failed to lower its landing gear, the runway watch fires a red pyrotechnic light signal, which indicates to the pilot he must not land.

An international signal, meaning aircraft in distress, is a single red pyrotechnic light displayed singly or in succession.

One green pyrotechnic light from the ground at an airfield grants the aircraft permission to land. This same signal FROM the aircraft at night means that the pilot is requesting permission to land, whereas by day, the pilot is requesting permission to land in any direction other than that authorized.

A white pyrotechnic light at night from a shore station means that the distress signal or plight has been observed and assistance has been summoned. In the daytime, an international white smoke signal means the trouble has been noted and assistance will be given as soon as possible.

An orange or white pyrotechnic light from an airfield means local recall. This signal may also be used in fog or mist or for any other reason to indicate the position of an airfield.

CHAPTER 11

AIRPORT TRAFFIC CONTROL

AIRPORT LAYOUT

The Air Controlman must have a thorough knowledge of the airport layout, airfield markings, and airfield lighting equipment to effectively control traffic on and in the vicinity of the airport.

SELECTION OF SITE

Why did the Wright brothers journey from Ohio to Kitty Hawk, North Carolina, to conduct their early tests? They were selecting a site, and for a very good reason. Their primary concern of the selection of a site was the prevailing wind conditions. They knew from earlier experiments, that their fragile and somewhat low powered craft needed the advantage of a steady wind to become airborne. The site at Kitty Hawk offered such an advantage.

In the early days of aviation a smooth field at the edge of town served quite adequately as an airport. Then, as aircraft became heavier and faster, and with the advent of instrument flying, bigger and more elaborate facilities had to be constructed. The airport of today is much more complex than in the past and many factors must be considered in selecting a site. Some of the major factors are adequate area, accessibility, weather conditions, and terrain.

Adequate Area

The site selected must afford a sufficient and suitable area for the required airport facilities. In the past years of aviation it was extremely difficult to accurately predict the rapid growth of aviation. Higher performance aircraft and the great volume of air traffic that grew so fast caused some airport areas to become inadequate very quickly. To add to the problem, cities and towns grew outward to meet the airport area. In planning the modern airport, careful consideration should be given to possible expansion in the future.

Accessibility

Another aim of site selection is to insure that adequate supply routes are available either by land, water, or by air. Railroads and surrounding highways naturally simplify the supply problem. When an airport is planned to serve a metropolitan area, it is necessary to locate the airport where it is easily accessible to the city and still does not create a hazard in the congested areas.

Many Navy airports exist for the primary purpose of supporting the fleet. In order to best serve this need they must be easily accessible. Their easy accessibility contributes not only economically, but to the combat readiness of fleet units.

Weather Conditions

Prevailing weather conditions should also be considered. By checking past weather bureau records of the area, future weather conditions can be predicted rather accurately. From an operational standpoint some things to consider are the frequency, severity, and persistence of wind, fog, snow, and rainfall. Additional items to be considered are the need for snow removal equipment, number and type of instrument landing aids, and elaborate drainage construction in areas of heavy rainfall. These factors figure greatly in the cost of construction and maintenance of any airport.

Terrain

A site with favorable topography is one located on high ground with sufficient slope for natural drainage and a reasonably level surface.

Rough or hilly terrain can easily become hazardous to low flying aircraft operating from an airport. In addition, rugged terrain can increase considerably the cost of construction.

The proposed area should be flight-tested for planning approaches to future runways. Special attention should be given to the possibility of shifting wind, downdrafts, and the presence of air eddies that may affect these approaches. From these tests it may even be determined that the proposed site is not a suitable one.

FACILITIES

Throughout the development and construction of airports, facilities have become more standard in the Navy. In keeping with this standardization, further studies of considerable scope and magnitude are presently underway due to progress in the development of aircraft and related installations. The facilities aboard any military airport are many and varied. The Air-Controlman must keep abreast of airport advances and the facilities that are available in order that he may properly handle and expedite air traffic.

Runways

A runway is that portion of the landing area, usually paved, upon which aircraft actually land and takeoff. Runway pavement is designed to meet rigid specifications under certain conditions and to resist jet blasts and fuel spillage. The number and orientation of runways are determined from an analysis of wind and other pertinent data. When more than one runway is considered for an airport, the primary runway is determined by the direction of maximum wind coverage (prevailing wind) to facilitate landings and takeoffs into the wind. The secondary and subsequent runways are oriented to provide the greatest overall wind coverage. This plan is generally the most widely followed. However, adjustments may be required for surrounding developments, local terrain features, excessive construction problems, or alinement of an instrument runway to suit all weather conditions. At airports where the volume of traffic would be restricted by the availability of only one runway, parallel runways may be incorporated either in the original design or added later as necessary.

Runway Overrun Areas

These areas are usually nonpaved, relatively smooth areas which extend beyond the ends of runways. A portion of this area is constructed of selected materials, compacted and stabilized. This stabilized area is essentially an extension of the runway. The primary purpose of this strip is to provide a reasonably effective deceleration area for aborting or overshooting aircraft. This area may also serve as an emergency all-weather access for firefighting, crash, and rescue equipment. Provisions are made at the upwind end of takeoff runways for a crash strip which is an extension beyond the overrun area. Takeoff runways are those runways whose takeoff usage exceeds 40 percent of total takeoffs. All obstructions are removed; and ditches, gullies, and embankments are leveled off into the general profile of the extended centerline of the runway to minimize damage to aircraft.

Some runways have paved overruns and the area is marked with yellow chevrons across the area. With this type marking, it becomes a nontouchdown area. At some stations these areas are called blast pavements; used primarily to prevent erosion of runway ends from propeller and jet blast. They are usually made of highway paving material and do not have runway-bearing strength.

Taxiways

A taxiway is a specially prepared area, or lane, over which aircraft usually operate under their own power to and from the landing and parking areas. Taxiways are normally constructed to the same specifications as the runways except for dimensions. A warmup area, usually an expanded portion of the taxiway adjacent to the end of the runway, is used for aircraft holding, engine warmups, and checking aircraft instruments and radio equipment. In any event, the warmup area must be of sufficient dimensions to permit aircraft to hold at least 100 feet clear of the runway in use.

Parking Areas

This is a hard-surfaced area located in the vicinity of hangars for the purpose of parking, servicing, and loading aircraft. They are connected to the runways by taxiways, and normally padeyes are sunk into the surface for tying down aircraft during storm conditions.

Mat Facilities

The mat is a large, hard-surfaced area usually located near the center of the field or at a common intersection of runways. It is often used for the operation of small aircraft and facilitates the taking off and landing of several aircraft at the same time. The mat is especially useful where pilot training is being conducted. The load limits of mat areas are often less than the regular runways; therefore, Air Controlmen assigned to fields which have these facilities should be aware of their load limitations.

Compass Calibration Pad

The compass calibration pad or compass rose is a special paved installation, ordinarily circular in design, used for calibrating the magnetic compass(es) in the aircraft and situated well clear of approach and departure paths of aircraft landing or taking off. The surface is marked every 15 degrees to indicate magnetic bearings beginning with magnetic north. The taxiway to the compass rose is generally placed perpendicular to the taxiway with the least traffic, and the compass rose location must be free from local magnetic influences. All metal used in the construction is either brass or bronze, because it will not affect magnetic instruments. Other metal objects should be kept clear of the area when the compass rose is in use. In calibrating an aircraft compass, all electrical equipment is turned on and the engines kept running to simulate actual flight conditions.

Wind Direction Indicators

The three principal types of wind indicators are the wind tee, the windsock, and the tetrahedron. (See fig. 11-1.)

The wind tee is similar in outline to a small aircraft. It is mounted on a pedestal and will weathercock into the wind, thereby indicating the wind direction. This free swinging characteristic affords the pilot a visual presentation of the exact direction from which the wind is blowing. If the tee is not alined perfectly with the runway being used, the pilot knows that he has to compensate his landing for a crosswind—the amount of compensation being roughly judged from the angle the tee is deviating from the centerline of the landing runway. Also, while taking off it is expedient for the pilot to have this same information. The wind tee may be lighted by one or more lights for nighttime use with green lights on the fore and aft bar and red lights on the crossbar.

AC.135

Figure 11-1.—Wind direction indicators.

The windsock has the appearance of a large stocking minus the foot. It is made of light, durable fabric and is secured to a mast by means of a swivel on the hoop at the large end. Air in motion passing through the windsock alines the windsock with the wind to indicate the direction from which the wind is blowing. The windsock has an advantage over the wind tee in that besides indicating the direction, it also gives an approximation of wind velocity.

The velocity of the surface wind can be approximated by comparing the angle of the windsock in its relation to the ground. The windsock will stand out parallel with the ground when the wind is 15 to 20 knots. (A steady wind greater than 20 knots will give the same indication; hence caution must be exercised if the windsock is the only available reference.) A gusty wind is indicated when the windsock alternately rises and falls rapidly. A calm wind is indicated when the windsock hangs limply at the mast. Gusty, shifting wind is denoted by the windsock swinging from side to side and rising and falling.

The type of fabric from which the windsock is constructed determines to a great extent how high it will rise in a given wind velocity. Thus, the fabric should be a standard type for all windsock construction in order for consistent approximations of wind velocities to be made. The windsock may be lighted for nighttime use.

The tetrahedron is the largest of the three wind indicators. The ideal location for this indicator is at a site easily visible from the ends of all runways. A 100-foot circular background of contrasting color, under the tetrahedron, increases the visibility of this indicator tremendously.

The tetrahedron is outlined at night by green lights on the starboard side and red lights on the port side, with green lights along the central ridge and spar. (See fig. 11-2) Tetrahedron lights flashing between sunset and sunrise indicate that the ground visibility is less than 3 miles or the ceiling is less than 1,000 feet, or both. Normally, when this condition exists, VFR operations are suspended and IFR operations placed into effect.

AIRFIELD PAVEMENT MARKING

Runway Markings

Runway numbers which appear near the approach end of all runways indicate the magnetic heading of the runway. The number assigned to a runway is one-tenth of the magnetic compass reading to the nearest whole number. This means that when a pilot lands toward the South with a compass reading of 168 degrees, he will be landing on runway 17. (If the last figure is 5 or more, select the next higher 10-degree increment.) In this example the nearest whole number is 170 degrees; so, by dropping the zero from 170 degrees or 1/10 x 170, the figure 17 is produced. This number will appear on the approach end of the runway.

If the inbound magnetic heading of a runway is less than 100 degrees, such as 070, 080, 090, etc., the first zero and the last zero are dropped, resulting in runways numbered 7, 8, and 9. (See fig. 11-3.)

At airports using multiple parallel runways L indicates left, R indicates right, and C indicates center. All numbers and letters are painted with reflective white paint and the paint may be applied solid or composed of 6-inch strips spaced 6 inches apart.

The runway centerline stripe is 3 feet wide on a primary runway and 2 feet wide on all other runways. They are painted white (reflective) and when placed on concrete pavement the stripe is edged with a 1-foot band of black paint. The runway centerline marking is formed by a broken line. At intersections of two or more runways, the centerlines are continued through the intersection.

To aid further in takeoff and landing guidance, there are runway side stripes in addition to the runway centerline stripe. The painting specifications are the same, except that the side stripes are solid instead of broken lines. (See fig. 11-3.) At intersections of two or more runways, the side stripes are continued on one runway only. Preference for the continuous runway stripe is given to the primary runway.

Navy markings also include runway distance markers which afford pilots information as to length of runways during landings and takeoffs. These markers are 4-foot square vertical signs painted international orange with white numerals and each has a hooded floodlight for night viewing. The numerals express, in decreasing order, the distance in thousands of feet of actual runway remaining. Only the first number appears on the sign; for example, 4 indicates 4,000 feet of runway remaining. The markers are mounted directly opposite each other on each side of the runway at 1,000-foot intervals

AC.136

Figure 11-2.—Tetrahedron lighting arrangements.

10613

AC.137

Figure 11-3.—Runway markings.

25 feet outboard of the runway edge and perpendicular to the runway centerline. Where runway intersections or taxiway entrances interfere, the longitudinal spacing may be varied, but in no case will markers along the last 3,000 feet indicate appreciably more runway than actually exists.

At some locations there are markings that are used for a specific purpose. One most common is an area used for field carrier landing practice (FCLP). In this instance an area is painted to simulate an aircraft carrier deck. Stations involved in testing new or modified aircraft sometimes require special markings in the course of conducting various tests. Fields that are used primarily for pilot training may have certain markings arranged so as to better accomplish this task.

Large signs are installed on both sides of the runway to mark the location of arresting gear (discussed later in this chapter). The signs are large (7 feet long) yellow plexiglass arrows with white letters on a black background. The signs are lighted. (See fig. 11-4.)

Taxiway Markings

Taxiway centerline stripes, like runway markings, give visual aid to pilots. A noticeable difference between runway and taxiway markings is that white markings are used on runways, whereas taxiway stripes are indicated with reflective yellow paint. Each taxiway is marked by a single centerline stripe 6 inches wide and continues onto the runway to the runway centerline (fig. 11-5) except at runway ends as in figure 11-3.

Holding post markers are also painted reflective yellow and consist of two solid lines and two broken lines. They are placed across

10614

AC.138
Figure 11-4.—Arresting gear signs.

the taxiway at right angles to the taxiway centerline. (See fig. 11-5.) These painted markings are used for holding aircraft 100 feet clear of the nearest runway edge. Ground traffic must not proceed beyond the holding post marker without a control tower clearance.

Another taxiway marking is the VOR/TACAN checkpoint triangle pavement marker. It is an equilateral triangle (a triangle with all sides equal), painted with an 8-inch stripe in yellow, with sides 5 feet long. From this checkpoint an aircraft is able to ground check his VOR/TACAN equipment prior to flight. There are usually several on an airport to facilitate ground checks regardless of the taxiway in use. (See fig. 11-6.)

The checkpoint is used in conjunction with a VOR/TACAN check sign. The sign is constructed of lightweight material, utilizing frangible supports, and placed 25 feet from the edge of the taxiway. It is painted with black lettering and has a hooded floodlight for night viewing. (See fig. 11-6.) The hood is provided so that the vision of pilots will not be impared during night operations. The information included on the sign is station identification, channel number or frequency, and magnetic bearing and distance to the VOR or TACAN station. The distance and bearing indicated are from the checkpoint, not the sign.

Deceptive, Closed, and Hazardous Area Marking

Where it is determined that an operational requirement exists, there are provisions for marking deceptive, closed, and hazardous areas.

A deceptive area is any surface or area which appears usable but which, due to the nature of its structure, is not intended for normal operational use by aircraft. All deceptive and closed area markings are painted with nonreflective yellow paint, except in the case of a displaced threshold arrow and bar which is painted with nonreflective white.

A closed area may be a runway, taxiway, or any other area that was once used but is no longer considered usable. It may be temporary, such as during construction, or permanently closed.

An example of various markings of deceptive, closed, and hazardous areas, both overall and detailed descriptions, are presented in figure 11-7. Study this figure carefully in addition to reading the text.

A hazardous area is an area or any permanent or temporary construction that presents a definite hazard to the operation of aircraft. Some examples are smoke stacks, antenna towers, buildings, and elevated tanks such as water supply tanks. When considered a hazard to flight, they are painted with aviation surface orange and white paint, normally in a checkerboard pattern. Where the predominating background does not afford a satisfactory contrast

AC.139
Figure 11-5.—Taxiway/runway intersection.

10615 41301

AC.140

Figure 11-6.—VOR/TACAN checkpoint and check sign.

with aviation surface orange, the use of chrome yellow paint is permitted.

A closed runway is marked with a cross composed of two yellow bands 10 feet wide and 60 feet long. They are placed in the center of the closed runway, with no specified minimum distance between crosses but they cannot be placed more than 1,000 feet apart. One cross is always placed near both ends of the closed runway and adjacent to other runways and taxiways. At night, red lights in the form of a cross are placed at the ends of the runway in sufficient numbers to make certain that the cruciform arrangement is clearly distinguishable.

A closed taxiway marking is quite similar to a closed runway marking; however, the cross formed by the yellow bands, or red lights at night measure just half the size of the runway marking. They are always placed at or near the entrance of the closed taxiway. There is no set minimum or maximum distance between the crosses since each one in effect denies the use of the affected area. (See fig. 11-7.)

Small holes, soft spots, etc., on the usable portion of landing fields, are marked by day with yellow flags or yellow pyramids and by night with red lights, to warn incoming pilots that the particular spots so marked are unsafe for landing.

When relatively large areas are unsafe for landing they are outlined by day with yellow flags and by night with red lights.

An entire area outlined as unusable is indicated by placing in its approximate center, a relatively large cross made up of yellow flags or strips of yellow fabric by day, or made up of red lights at night.

AC.141

Figure 11-7.—Marking at deceptive, closed, and hazardous areas.

Closed land targets are marked by two yellow strips 3 feet wide and 200 feet long placed in the shape of an X adjacent to the target. Closed water targets are marked by yellow dye placed in the water immediately surrounding the target.

Overrun areas are constructed primarily to provide a reasonably safe deceleration area for aborting or overshooting aircraft, with minimum danger to personnel and damage to aircraft. When these areas are paved they could be easily mistaken for a landing area. When this possibility exists, runway overrun markings are used. These are in the form of chevrons painted nonreflective yellow, and the apex of the chevron points toward the runway. The stripes forming the chevron form a 45-degree angle away from the runway centerline extended and are 3 feet in width. There is no specified minimum size of the chevron, but the overall dimensions cannot exceed 100 feet. They are placed on the paved over-run, along the runway centerline extended, 100 feet apart. (See fig. 11-7.)

When the threshold is moved forward on a runway, the area leading to the new location must be adequately marked to prevent aircraft from landing short of the newly established landing area. This marking is composed of a series of arrows painted nonreflective white, with an overall length of 120 feet and with 80-foot spaces between them. They are placed along the runway centerline and point toward the new threshold with the last arrow point placed 5 feet from the threshold bar. The threshold bar itself is a nonreflective white bar 10 feet wide placed across the runway perpendicular to the runway centerline (See fig. 11-7.)

Runway, taxiway, and apron shoulder markings all have much in common. All of these markings are painted nonreflective yellow with a 3-foot wide stripe beginning at the pavement edge, and placed 100 feet apart. Runway markings are placed at a 45-degree angle toward the approach end of the runway beginning at the runway midpoint. Taxiway and apron shoulder markings are perpendicular to the edge of the area. (See fig. 11-7.)

Blast pavement markers are nonreflective yellow stripes 3 feet wide and 50 feet long. They are placed in areas where jet and propeller blast should be directed when making engine runups at high power settings. Usually these markings are placed near the ends of runways. However, some areas may be established at other points on the airport specifically for maintenance checks. (See fig. 11-7.)

Remember that deceptive, closed, and hazardous area markings are only used when and where they are needed. A particular airport may have all, some, or none of these markings.

FIELD LIGHTING SYSTEMS AND OPERATION

Airport field lighting systems have been standardized by the Air Force, Navy, and the FAA in order to present a uniform and unmistakable appearance so that flight personnel who

10617

are familiar with the adopted standards may readily interpret the lighting aids at any airfield. These standards specify the location, spacing, and color of lighting components in use.

A field lighting system is composed of runway lighting and other lighting aids with necessary controls and power supply. All the lighting aids are considered in this section even though their installation is determined by the mission of the airport. It is necessary that the Air Controlman have a thorough knowledge of these lighting standards as well as the essential function and operating rules of the separate components.

Airport Beacons

A rotating beacon is located on the highest elevation available and must be at least 20 feet above the control tower floor.

The rotating airport beacon has a vertical light distribution such as to make it most effective at angles of one to three degrees above the horizontal from its site; however, it can be seen well above and below this peak spread. Rotation is in clockwise direction when viewed from above. It is always rotated at a constant speed which produces the visual effect of flashes at regular intervals. Those flashes may be of one color or may be of two colors alternately. (See chapter 8.) This beacon rotates at the rate of 12 to 15 revolutions per minute.

Where white and green or white and yellow color combinations are installed, the lights of different color are separated by 180 degrees. Rotating beacons are placed so that they are not closer than 750 feet to the centerline or extended centerline of the nearest runway.

Operation of an airport rotating beacon during the hours of daylight, means that the ground visibility in the control zone is less than 3 miles and/or the ceiling is less than 1,000 feet and that a traffic clearance is required for landing, takeoff, and flight in the traffic pattern.

Runway Lighting

Runway lights and threshold lights form the outline of the runway for night operations. The runway lights are located along both sides of the runway, extending the entire length. The spacing of these lights approaches but does not exceed 200 feet and can be installed as close as 70 feet to reduce a large gap in the lighting pattern of an intersection. Runway lights are white in color.

Threshold lights are green in color and are placed on each side of the runway ends. They form, in effect, green bars of light. The number of lights used in this corner group system will vary due to various widths of runways. Regardless of the number of lights installed, they will give the pilot the exact indication of where the landing area begins.

Both runway and threshold lights operate on the same control for a given runway. These controls are on a master control panel in the control tower. Runway lights are turned on for inbound aircraft as soon as the pilot reports in the control zone and are turned off when no longer needed. For outbound aircraft the runway lights are lighted as the aircraft approaches the takeoff position and turned off when no longer needed.

All-weather air stations have high intensity runway lights installed. The intensity or brightness of the runway lights can be varied by a selection switch on the lighting control panel in the control tower. There are five settings which may be selected with number 1 being the lowest and number 5 the highest. High intensity runway lights intensity settings may be operated as prescribed by local procedures or as requested by a pilot for his operation. Table 11-1 is a guide for determining the appropriate intensity setting.

Runway End Identifier Lights

Some facilities have runway end identifier lights installed. These are bluish white lights of the condenser discharge type (flashing) which identify the runway threshold. One such light, where installed, is located on each side of the runway end. These lights are normally connected

Table 11-1.—High intensity runway lights settings.

Step	Day visibility	Night visibility
5	Less than 1 mile	When requested
4	1 to 2 miles	Less than 1 mile
3	When requested	1 to 3 miles
2	When requested	3 to 5 miles
1	When requested	More than 5 miles

10618

Figure 15-2. —(A) Block diagram showing functions performed by a typical radar timer; (B) synchrogram of control pulses furnished by the timer shown in figure 15-2 (A).

blank the screen when signals are not to be received.

An important function of any radar set is the determination of range of the targets observed. The methods of range determination vary. Some use a simple transparent overlay (upon which ranges are marked) for the indicator screen. Others have complex circuits used for very accurate range measurements.

One method is the use of rangemarkers generated in the timer. The markers are pulses of very short duration, as shown in waveform

1059 1060 1058

to the runway light switch in the control tower and operate for the runway selected on that switch. An additional switch is provided to allow runway light operation with the runway end identifier lights off.

Runway Centerline Lighting System

Runway centerline lights, where installed, consist of a single row of lights at uniform intervals along the centerline of the runway to provide a continuous lighting reference from threshold to threshold. The lights may be installed on a primary and secondary runway. On/off and brightness controls for individual runway centerline lights are provided in the control tower. Runway centerline lights are white lights. The intensity selected should be the same as that selected for the high intensity runway lights.

Approach Lights

Approach lights of varying tvpes, colors, and construction have been specifically developed to meet civil and military requirements. These lights are installed in an area extending outward from the threshold of the instrument runway, and are usually the pilot's first visual contact with the ground under extremely low visibility conditions. Electronic landing aids, such as GCA and ILS, are used to bring the pilot down to the approach minimums. Approach lights are required for final alinement with the runway, and runway lights are required to complete the landing.

High-intensity incandescent lights penetrate somewhat farther through fog, smoke, or rain than neon lights. Several types of high-intensity approach lights have been installed in the United States, taking the place of the neon system.

The current system being installed at Navy facilities is called Centerline Approach Lighting System (U.S. Standard (A)). It consists of a series of crossbars of lights (normally 3,000 feet) with condenser discharge (sequence flashing) centerline lighting that coincides with the runway centerline lighting, that indicates the approach to, and threshold, of the runway. The intensity of the approach lights can be varied from the control tower. To be most useful, the lights must be bright enough to penetrate the overcast effectively without blinding the pilot or producing halo effects. Different intensity settings are needed for day and night use. The operation and intensity setting selected may be determined by local procedure and instructions. Table 11-2 is a guide for determining the appropriate approach lights intensity settings.

Visual Approach Slope Indicator (VASI)

VASI is designed to provide by visual reference the same information that a glide slope of an ILS provides electronically. It provides a 2 1/2- to 3-degree visual glide slope within the approach zone which a pilot can see and use for descent guidance during an approach to a landing.

The standard installation consists of 12 light source units arranged in light bars of 3 units placed on each side of the runway opposite the 600-foot mark, and three units on each side of the runway opposite the 1,300-foot mark. (See fig. 11-8.) Each light unit projects a beam of light having a white color in the upper part and a red color in the lower part. The light units are so arranged that the pilot, during an approach, would see one of the combinations shown in table 11-3.

The VASI can normally be seen at a distance of 4 to 5 miles, and at greater distances at night. The intensity of the VASI system is controllable at some installations while at others the intensity is controlled by an electronic device. Where controllable, the controls are located in the tower as is the on/off switch. Normally the VASI system is left on at all times; however, local procedure and instructions may require otherwise.

Table 11-2.—High intensity approach lights settings.

Step	Day visibility	Night visibility
5	Less than 1 mile	When requested
4	1 to 3 miles	When requested
3	3 to 5 miles	Less than 1 mile
2	When requested	1 to 3 miles
1	Greater than 5 miles	Greater than 3 miles

10619

10619

AC.142

Figure 11-8.—Visual approach slope indicator.

Taxiway Lighting

Taxiway lights, which are blue in color, have a variable spacing distance, depending upon the length of a straight taxiway segment or radius of curve of a taxiway turn. On a straight segment over 200 feet in length, the space between lights may approach but not exceed 200 feet. On a straight segment of 200 feet or less, the distance between lights may approach but not exceed 50 feet. Taxiway lights marking a curved edge of a taxiway follow the rule that the sharper the radius of curvature, the closer the lights are placed. In no case will there be less than three taxiway lights on any one taxiway.

Two blue lights spaced 5 feet apart and placed on each side of a taxiway entrance into (or exit from) a runway or parking area are called entrance-exit lights. These lights are not installed at intersections of taxiways or at locations that are normally runway entrances or exits.

Table 11-3.—VASI glide slope presentation.

Aircraft position	Presentation	
Above the glide slope	white	white
	white	white
On the glide slope	red	red
	white	white
Below the glide slope	red	red
	red	red

The control system for taxiway lights is designed to permit the lighting of combinations of individual taxiways necessary to provide any required lighted taxiing path. The taxiway lights are turned on as soon as the pilot of an aircraft is cleared to taxi out and turned off when the aircraft is on the runway or another taxiway. For inbound aircraft, they are turned on as the aircraft approaches the taxiway to be used and turned off when the aircraft is parked.

Floodlights

Mobile and portable floodlights have superseded the older type of permanently mounted runway floodlights. The field lighting truck is a mobile unit to provide emergency lighting. The portable floodlight is for emergency use, principally at outlying fields where floodlighting may be required for the landing area.

Floodlights are turned on for outbound aircraft when the pilot has taxied onto the runway and is facing the direction for takeoff. They are turned off when the aircraft has cleared the edge of the field, or when requested by the pilot. For inbound aircraft, the floodlights are turned on when the aircraft is identified near the field unless the pilot requests they be left off. In the latter event they are lighted briefly, before the aircraft enters the landing glide, to ascertain that the runway to be used is clear of obstacles. If the floodlights are used for landing, they are turned off when the aircraft has cleared the runway.

Obstruction Lights

Obstruction lights are located on all elevated obstructions on the airport and on all other obstructions within a given glide angle of an airport. They are red in color and are lighted from sunset to sunrise and during daytime when flight visibility is restricted.

Boundary Lights

Airport boundary lighting is no longer in general use; however, some older fields are still equipped with these aids. When used, the boundary lights are spaced around the perimeter of the landing area and are orange in color. These lights are in operation from sunset to sunrise.

10620

At airports where no boundary lights are installed (or when boundary lights are inoperative), runway lights on the runway most nearly alined into the wind, or the "calm wind" runway when appropriate, must be lighted between sunset and sunrise.

With the exception of the rotating beacon, the commanding officer or airport manager may establish hours of operation of the field lighting system NOT in accordance with the hours of operation heretofore discussed. In such cases, however, the commanding officer or airport manager must assume responsibility when field lighting is available on a request basis.

Wheels-Up/Runway Waveoff Lights

Wheels-up/runway waveoff lights consist of six clusters of three red lights located on each side of the runway starting approximately 800 feet from the runway threshold and spaced approximately 800 feet apart. Additionally, a wheels-up light bar is located approximately 1,000 feet outboard of the runway threshold on the same side of an imaginary extension of the runway as the control tower. (See fig. 11-9.) The lights face landing aircraft and are turned in toward the runway centerline. The lights can be controlled from the wheels watch position and the Landing Signal Officer (LSO) platform. When activated, a flashing device causes the lights to flash 90 times per minute with equal on and off time. The flare gun warning system previously used is being replaced by this system.

Fresnel Lens Landing System

Many facilities have a Fresnel Lens optical landing system installed along the side of a heavily used runway for use in field carrier landing practice and for pilots to keep proficient using this type of landing approach. The unit is the same as that installed on aircraft carriers. An example of such an installation is shown in figure 11-9.

CONTROL TOWER

The key facility of the airport operational system is the control tower. It is elevated to a suitable height to afford the maximum visibility of the airport and the immediate area. The primary objective of the control tower is to promote the safe, orderly, and expeditious movement of air traffic. This includes the following:

1. Aiding pilots in preventing collisions between aircraft and between obstructions and aircraft in the movement area.
2. Expediting and maintaining an orderly flow of air traffic.
3. Assisting the person in command of an aircraft by providing such advice as may be necessary for the safe and efficient conduct of a flight.
4. Notifying appropriate organizations regarding aircraft known or believed to be in need of search and rescue aid, and assisting such organizations as required.

The control tower exercises control of all aircraft operating on and around an airfield and all movements of aircraft must have prior approval from the Control Tower. This includes instructions and permission to tow, taxi, takeoff, land, and related aircraft operations (except where preventive control has been authorized.)

NOTE: Preventive control differs from other airport traffic control in that repetitious, routine approval of pilot action is eliminated. Controllers intervene only when they observe a traffic conflict developing.

COMBINED RESPONSIBILITIES

Both controllers and pilots are responsible to each other for good communications, coordination, and cooperation. These three factors are not separate entities but must be considered as different parts of responsibility which are shared by pilots and air traffic control personnel. Some of these responsibilities are set forth in publications, while others are not delineated as a regulation or a rule but are recognizable as definite responsibilities of a controller since his profession is one of service-that of aiding the pilot to accomplish a safe flight.

AUTHORIZED CONTROLLERS

Only those naval personnel properly qualified in accordance with the current OpNav instruction 3722.6 can exercise the control of air traffic. Additionally, this instruction requires that personnel exercising tower air traffic control possess an FAA Control Tower Operator Certificate (CTO).

TOWER OPERATING POSITIONS AND RESPONSIBILITIES

Establishment of controller positions varies according to local requirements and type of

10621

AC.143

Figure 11-9.—Wheels-up/runway waveoff lights.

facility, but those included in most control towers are Local Control position, Ground Control position, and Approach Control position.

The primary duties of the tower supervisor are to direct activities of a tower under the general supervision of the leading chief and/or watch officer. He supervises all positions of operation and directs the training of new personnel.

The following types of messages are ordinarily transmitted by the position indicated in the following paragraphs.

1. Local controller—issues information and clearances to air and vehicular traffic operating on the landing area, to VFR traffic operating in the control zone, and to IFR traffic released to local control position.

2. Ground control—assists other operating positions by handling taxiing aircraft and vehicular traffic on the landing area.

3. Approach control—provides separation between all aircraft operating IFR within the designated area of jurisdiction through application of separation standards.

At a Radar Air Traffic Control Facility, approach control would be located in the RATCC itself instead of the tower.

Some facilities use a flight data position, the duties of which consist of receipt, posting, and relaying flight data for the other positions and assisting in the operation of the tower as directed.

10622

AIRPORT TRAFFIC CONTROL PROCEDURES

Airport traffic control service is based only upon observed or known traffic and airport conditions which might, in the Air Controlman's judgment, constitite a hazard. These include parachutists within the control zone, vehicular traffic, large flocks of birds in the vicinity of the airport, and temporary obstructions on or near the airport.

Specific approval or disapproval for movement of vehicles, equipment, or personnel on the movement area is issued via radio or directional light gun. Approval of specific situations should not be qualified by conditional phrases such as BEHIND LANDING TRAFFIC, or AFTER THE DEPARTING AIRCRAFT.

A clearance to take off, land, or touch-and-go can only be denied on the basis of traffic conditions, except in the case of a closed runway or below minimum visibility conditions. Clearance for a low approach can only be denied on the basis of traffic conditions.

Should a pilot request to use a closed runway, he should be informed of the fact that the runway is closed and if necessary, the appropriate parts of the NOTAM applying to the runway should be quoted.

Any message related to an aircraft by the tower should include the source of the message.

EXAMPLE: OPERATIONS OFFICER ADVISES, or SQUADRON DUTY OFFICER REQUESTS (message).

A pilot's request to cross an airport traffic area at speeds in excess of the speed limit for an airport traffic area (200 knots for turbine powered aircraft and 156 knots for reciprocating engine powered aircraft) may be approved if traffic conditions permit. However, speeds in excess of 250 knots should not be approved unless the pilot advises that a higher minimum speed is required, or normal military operating procedures require such speeds.

If a controller should observe an abnormal condition of an aircraft, the pilot of such aircraft should be informed.

EXAMPLE: REAR BAGGAGE DOOR APPEARS OPEN.

When a pilot has any doubt that his landing gear is down and locked, he will notify the control tower. The controller would then instruct the pilot to perform a low pass in front of the tower for the purpose of a visual check. The controller would then relay to the pilot the results of the visual check.

EXAMPLE: LANDING GEAR APPEARS DOWN AND IN PLACE; or, NOSE GEAR DOES NOT APPEAR IN PLACE.

Should any doubt exist after a visual check, the controller would alert the crash and rescue equipment and the aircraft would make a precautionary landing. After the landing rollout, the aircraft should not turn off the runway until ground personnel have made a visual check of the landing gear and installed the gear pins.

Unusual maneuvers of an aircraft within an airport traffic control area should not be approved or requested if such maneuvers are not essential to the performance of the flight.

Wake Turbulence

Turbulence generated by aircraft which was once thought to be prop wash is now categorized as "thrust stream turbulence" and "wingtip vortexes." These categories of turbulence are collectively termed WAKE TURBULENCE.

Thrust stream turbulence is the disturbance of air behind aircraft caused by propeller action or jet blast. It could be a hazard to aircraft operating on the ground close behind larger aircraft making an engine runup. At distances of 400 to 500 feet, thrust stream turbulence should not constitute a serious hazard except for aircraft landing or taking off in the immediate area of another aircraft on the ground making an engine runup.

Wingtip vortexes are trailing masses of disturbed air created by the wing of an aircraft as it produces lift. An aircraft creates two such vortexes with rotational air movement, one trailing each wingtip. The rollup process is normally complete about 200 to 400 feet behind the aircraft. Once formed, the vortexes extend and may be hazardous for an undetermined distance behind the generating aircraft and may last from 3 to 5 minutes. The turbulence is directly related to the weight, wingspan, and speed of the aircraft. Its intensity is directly proportional to the weight, and inversely proportional to the wingspan and speed of the aircraft. The heavier and slower the aircraft, the greater will be the intensity of the turbulence. Thus, modern large transport aircraft will create maximum turbulence during takeoff and landing at or near maximum gross weights.

Another factor to consider is the vertical and lateral movement of the vortexes. Vortexes

generated more than 100 feet above the surface will drop vertically in a no-wind condition a distance equal to approximately one-half the wingspan of the generating aircraft. At that point they start to curve outward and spread laterally away from the aircraft track. Additionally, both the vertical and lateral movement will be affected by and move with the encompassing airmass.

If a tower controller should foresee the possibility of wake turbulence, cautionary information should be issued to the pilot of the aircraft concerned.

EXAMPLE: CAUTION WAKE TURBULENCE, C ONE FORTY ONE JUST DEPARTED.

Since the existence and effect of wake turbulence are unpredictable, a controller is not responsible for anticipating the need for such information in all cases. However, controllers must be especially alert for a situation wherein the possibility of aircraft under their jurisdiction encountering wake turbulence exists and insure that the affected pilots are advised. This will enable the pilot to avoid the suspected hazardous area and enhance the safety of flight.

Traffic Information

Local traffic information is issued when in the judgment of the controller such information is necessary in the interests of safety or when requested by a pilot.

Vehicles, equipment, or personnel on the movement area are described in a manner which will assist pilots in recognizing them.

Military air traffic is described as follows:

1. Military designator, with numbers spoken in group form.
2. Service and type with the following exception.
3. Type only, if no confusion or misidentification is likely.

EXAMPLES: F-FOUR; NAVY FIGHTER; or, FIGHTER.

Air carrier traffic is described as follows:

1. Manufacturer's name or model.
2. Add company name or other identifying features if confusion or misidentification is likely.

EXAMPLES: VISCOUNT; AMERICAN DC-NINER; or, UNITED VISCOUNT.

General aviation air traffic is described as follows:

1. Manufacturer's model, name or designator.
2. Add color when considered advantageous.

EXAMPLES: TRI-PACER; CESSNA THREE TEN; or, GREEN APACHE.

When it is necessary to make a hurried, brief transmission of traffic information, the aircraft type may be omitted.

The relative position of traffic must be issued to pilots in an easily understood manner, such as TO YOUR RIGHT, or AHEAD OF YOU, instead of local terminology or compass directions.

EXAMPLES: TRAFFIC U ELEVEN ON DOWNWIND LEG TO YOUR RIGHT; or, F FOUR BE INBOUND FROM INITIAL, RUNWAY SIX.

Field Condition Information

Pertinent field condition information necessary for an aircraft's safe operation is issued in time for it to be useful to the pilot. The following information concerning field conditions must be issued to pilots concerned:

1. Construction work on or immediately adjacent to the movement area.
2. Rough portions of the movement area.
3. Braking conditions caused by ice, snow, slush, or water.
4. Snowdrifts or piles of snow on or along the edges of the area and the extent of any plowed area.
5. Parked aircraft on the movement area.
6. Irregular operation of part or all of the field lighting system.
7. Any other field conditions considered pertinent by the controller.

Description of field conditions issued should be stated clearly and concisely.

EXAMPLES: MOWER TO THE LEFT OF RUNWAY; or, MEN AND EQUIPMENT NEAR THE APPROACH END OF THE RUNWAY.

Weather Information

The tower may transmit to pilots or other ATC facilities, without consulting weather service personnel, any elements of weather information derived directly from instruments, from radar, or received as a pilot report. Observed weather conditions such as LARGE BREAKS IN THE OVERCAST, VISIBILITY LOWERING TO THE SOUTH, or similar statements which do not include specific values may be transmitted. Terminal radar control facilities should inform towers for which they provide approach control service about storm areas observed on radar.

10624

10652

Elements of weather information which include specific values (such as ceilings and visibility) may not be transmitted unless the observing controller is properly certificated and acting as a weather observer, or the weather observation was made or verified by weather service personnel.

Controllers should inform local weather service personnel of any differences between weather conditions observed from the tower and those reported by weather service.

Visibility observations may be taken from the control tower during periods when the visibility at the usual point of observation is less than 4 miles. Control tower personnel who make official visibility observations must be properly certificated. Weather service personnel should be advised whenever the visibility is apparently reduced to less than, or has risen to equal or exceed, 4 miles.

Current weather changes should be forwarded to the appropriate control facility as follows:

1. When the official weather decreases to less than or increases to exceed:

a. 1,000 foot ceiling or the highest circling minimum, whichever is greater.

b. 3 miles visibility.

2. Changes which are classified as special weather observations during the time the ceiling is below 1,000 feet or the highest circling minimum, whichever is greater; or 3 miles visibility.

Towers at airports where military turbojet enroute descents are routinely conducted should also report these changes to the appropriate ARTCC even if it is not the controlling facility.

Bird Activity Information

Bird activity information including position, size and species (if known), and their course of flight should be issued to pilots of aircraft concerned for at least 15 minutes after receipt of the information from pilots or adjacent facilities. This time may be reduced when either visual observations or subsequent reports reveal that the activity is no longer a factor.

Visual Signals

Air traffic control light signals are used to control aircraft and movement of vehicles, equipment, or personnel on the movement area when radio communications cannot be employed. These signals are in accordance with figure 10-1 in chapter 10 of this training manual.

To obtain an acknowledgment from aircraft equipped with a receiver only, a controller should request the pilot of the aircraft to move the aileron or rudders on the ground, or rock the wings when airborne, during daylight hours; or, blink the navigation or landing lights at night.

Runway Use

Except where a "runway use" program is in effect, the selection of the runway to use, or the duty runway, is as follows:

1. The runway most nearly alined with the wind, when the wind velocity is 5 knots or more.

2. The calm wind runway, when the wind velocity is less than 5 knots.

Use of a runway other than those mentioned above is permissible if it will be operationally advantageous or if it is requested by a pilot. If a pilot prefers to use a runway different than that specified by a controller, he is expected to advise the controller accordingly.

Runway use programs for large aircraft and turbojet aircraft may be established at some airports. Where such programs are established, runway assignment is affected by consideration of noise sensitive areas and noise abatement benefits. Acceptance or refusal of such assignments is still the pilot's prerogative.

Both wind direction and velocity must be issued when authorizing the use of runways, even though the wind velocity is less than 5 knots and the calm wind runway is to be used. This information is necessary since some aircraft are adversely affected by a tailwind or crosswind component, and pilots must be aware of the exact wind condition to make the decisions necessary for a safe flight. Therefore, the wind condition is described as "calm" only when the velocity is actually zero.

Runway Conditions

At those facilities affected by winter weather conditions, runway condition and braking action is important information which must be relayed to pilots when adverse conditions exist on the landing area. The following contractions have

10625

10625

been established to indicate the runway surface condition:

1. WR . . . . . Wet runway.
2. SLR. . . . . Slush on runway.
3. LSR. . . . . Loose snow on runway.
4. PSR . . . . . Packed snow on runway.
5. IR. . . . . Ice on runway.
6. P. . . . . Patchy (used as a suffix to the condition reading. See example.)

Procedures have been established for determining decelerometer readings to indicate the effect of the runway condition on braking action. This is called runway condition reading (RCR). A decelerometer is an instrument used in a moving vehicle which indicates the amount of deceleration when the brakes are applied. Average readings are taken and expressed in two digit numbers from 00 to 25, giving an indication of braking action as follows:

1. 00 to 05 . . . . . Braking nil.
2. 06 to 12 . . . . . Braking poor.
3. 13 to 18 . . . . . Braking fair.
4. 19 to 25 . . . . . Braking good.

When relaying runway conditions to aircraft, Navy controllers should state the runway surface condition and the RCR reading, and give a description of the braking action.

EXAMPLE: CODED—IR RCR07 P. SPOKEN—ICE ON RUNWAY, RCR ZERO SEVEN, BRAKING POOR, PATCHY.

Separation

Air traffic should be controlled in accordance with established traffic and taxi patterns. The controller must establish a sequence of arriving and departing aircraft by issuance of instructions and information that require pilots of aircraft to adjust flight or ground operation as necessary to achieve proper spacing or separation.

To assist the controller in determining the minimum interval between various operations, the following categories of aircraft have been established.

1. Category 1. —Lightweight, single-engine, personal type, propeller driven aircraft. (Does not include high performance aircraft such as the T-28.)

2. Category 2. —Lightweight, twin-engine, propeller driven aircraft weighing less than 12,500 pounds, such as the U-11 and C-45.

3. Category 3. —All other aircraft such as the high performance single engine, heavy twin-engine, four engine, and turbo jet aircraft.

The application of procedures and minimums, local deviations or application of reduced separation, and conditions allowing such operations are the same as those listed under IFR CONTROL PROCEDURE later in this chapter.

SIMULTANEOUS OPERATIONS ON PARALLEL RUNWAY.—Simultaneous, same direction operations may be authorized on parallel runways, or landing strips, under the following conditions:

1. Operation must be conducted in VFR conditions unless visual separation is applied between aircraft concerned by the tower controller or pilots of the aircraft conducting the operation.

2. Two-way radio communications must be maintained with the aircraft involved and pertinent traffic information must be issued.

3. The distance between the runways, or landing strips, must be in accordance with table 11-4.

NOTE: If two categories of aircraft are involved, the greater distance must be applied.

Simultaneous, opposite direction operations on parallel runways or landing strips, or on a runway and a parallel landing strip, may be authorized under the following conditions:

1. Operations must be conducted in VFR conditions.

2. Two-way radio communications are maintained with the aircraft involved and pertinent traffic information is issued.

Table 11-4.—Criteria for simultaneous, same direction operations on parallel runways.

Aircraft type	Minimum distance in feet between.	
	Runway center-lines	Adjacent edges of runway or landing strips
Light-weight, single-engine, propeller-driven	300	200
Twin-engine, propeller-driven	500	400
All others	700	600

10626

Table 11-5.—Criteria for simultaneous, opposite direction operations on parallel runways.

Time of operation	Minimum distance in feet between.	
	Runway center-lines	Adjacent edges of runways or landing strips
Between sunrise and sunset	1400	1400
Between sunset and sunrise	2800	Not authorized

AC.144

Figure 11-10.—Separation of departing aircraft.

3. The distance between the runways or landing strips must be in accordance with table 11-5.

SEPARATION OF DEPARTING AIRCRAFT.—Departing aircraft are separated from other aircraft using the same runway by insuring that they do not begin takeoff roll until one of the following conditions exist:

1. The other departing aircraft has crossed the runway end, or is airborne and turning to avert any conflict. (See fig. 11-10.)

2. Provided that distances by reference to suitable landmarks can be determined, the other departing aircraft need only be airborne if the following minimum distances exist between aircraft (fig. 11-11):

a. If only category 1 aircraft are involved - 3,000 ft.

b. If either aircraft is a category 2 aircraft - 4,500 ft.

c. If either aircraft is a category 3 aircraft - 6,000 ft.

3. A preceding arriving aircraft has taxied off the runway. (See figure 11-12.)

Departing aircraft are separated from another aircraft using an intersecting runway by insuring that it does not begin takeoff roll until one of the following conditions exists:

1. The preceding departing aircraft has passed the intersection or is airborne and is turning to avert any conflict. (See fig. 11-13.)

2. The preceding arriving aircraft has taxied off the landing runway, or completed the landing roll and will hold short of the intersection, or has passed the intersection. (See fig. 11-14.)

SEPARATION OF ARRIVING AIRCRAFT.—Arriving aircraft are separated from other aircraft using the same runway by insuring that the arriving aircraft does not cross the landing

AC.143

Figure 11-11.—Separation of different category departing aircraft.

10627

AC.146

Figure 11-12.—Separation between departing and a preceding arriving aircraft.

AC.148

Figure 11-14.—Separation between departing and arriving aircraft using intersecting runways.

threshold until one of the following conditions exists:

1. The other arriving aircraft has taxied off the runway. (See fig. 11-15.)

2. Between sunset and sunrise, if distances by reference to suitable landmarks can be determined and the other aircraft has landed, the preceding arrival need not clear the runway if the following minimum distances from the landing threshold exist (fig. 11-16):

a. When a category 2 aircraft is landing behind a category 1 or 2 aircraft —4,500 feet.

b. When a category 1 aircraft is landing behind a category 1 or 2 aircraft—3,000 feet.

3. The other departing aircraft has crossed the end of the runway. (See fig. 11-17.)

4. If distances by reference to suitable landmarks can be determined and the preceding departure is airborne, it need not have crossed the runway end if the following minimum distances from the landing threshold exist (fig. 11-18):

a. When only category 1 aircraft are involved—3,000 feet.

b. When either aircraft is a category 2 aircraft—4,500 feet.

c. When either aircraft is a category 3 aircraft—6,000 feet.

An arriving aircraft is separated from another aircraft using an intersecting runway by insuring that the arriving aircraft does not cross the landing threshold until one of the following conditions exists:

1. The preceding departing aircraft has passed the intersection or is airborne and turning to avert any conflict. (See fig. 11-19.)

2. A preceding arriving aircraft has taxied off the landing runway, completed landing roll and will hold short of the intersection, or has passed the intersection. (See fig. 11-20.)

NOTE: Touch-and-go, or low approach operations are two separate operations; i.e., the aircraft is considered as arriving aircraft until

AC.147

Figure 11-13.—Separation between departing aircraft using intersecting runways.

AC.149

Figure 11-15.—Separation between arriving aircraft.

10628

10628

(5) of figure 15-2 (B). These pulses, separated by specific intervals of time, are applied to the indicator in the same manner as video signals. They appear as straight lines on a B-type indicator or circles on a PPI-type indicator. (NOTE: Indicators are discussed in chapter 17 of this course.)

All the control pulses described and illustrated in figure 15-2 (B) are repetitive; that is, they appear once during each cycle of operation. The timer furnished several series of pulses, each having the proper waveform and time relationship to the others. In order that a timer may provide these control pulses, it must contain the following elements:

1. A master oscillator to determine the pulse repetition frequency (PRF). This is usually a multivibrator.
2. A means of forming pulses of the desired shapes and time relations (usually miltivibrators, blocking oscillators, and delay circuits).
3. Circuits capable of matching the waveform generator to either its output circuit or to a transmission line without distortion of the waveform (the cathode follower).

All of the previously mentioned circuits have been discussed in detail in the Navy Training Course, Basic Electronics, NavPers 10087-B.

Multivibrator Timer

The multivibrator type master oscillator is used in most airborne radar systems, and is usually referred to as the heart of the radar. The multivibrator timer may do the following:

1. Establish the pulse recurrence frequency.
2. Trigger the rangemarker generating circuits.
3. Trigger the sweep circuits.
4. Trigger the transmitter.
5. Establish a time base for the intensity gate.

Figure 15-3 is a simplified block diagram of a synchronizer utilizing a multivibrator as the master timer.

The master trigger multivibrator is free running. Its output frequency, which is determined by the time constants of the RC networks in the grid circuits determines the PRF of the set. Figure 15-4 is an illustration of a free-running multivibrator. C1R3 and C2R4 make up the RC networks in the grid circuits.

The output taken from the plate circuit is fed to the fixed delay circuit for firing the transmitter and the variable delay, or directly to the range sweep circuits if no sweep delay is to be employed. (Refer to fig. 15-3.) The

Figure 15-3. —Simplified block diagram of a synchronizer using a multivibrator master timer.

AC.151

Figure 11-17.—Separation of arriving and preceding departing aircraft.

it touches down (for touch-and-go) or crosses the landing threshold (for low approach) and thereafter becomes a departing aircraft.

SEPARATION OF HELICOPTERS.—Departing helicopters are separated from other helicopters by insuring that they do not takeoff until one of the following conditions exist:

1. A preceding, departing helicopter has proceeded away from the takeoff area. (See fig. 11-21 (A).)

2. A preceding, arriving helicopter has taxied off of the landing area. (See fig. 11-21 (B).)

An arriving helicopter is separated from other helicopters by insuring that it does not land until one of the following conditions exists:

AC.152

Figure 11-18.— Separation of arriving and preceding departing aircraft of different category.

10629

AC.153

Figure 11-19.—Separation of arriving and other departing aircraft using intersecting runways.

AC.154

Figure 11-20.—Separation of arriving and other arriving aircraft using intersecting runways.

1. A preceding arriving helicopter has come to a stop or taxied off the landing area. (See fig. 11-22.)

2. A preceding, departing helicopter has proceeded away from the landing area. (See fig. 11-23.)

Helicopters may be authorized to conduct simultaneous landings or takeoffs if the distance between the landing and takeoff points is at least 200 feet and the courses to be flown do not conflict. (See fig. 11-24.)

NOTE: Surface markings would have to be referred to, in order to determine the minimum distance between helicopters, or the pilots of the helicopters may be instructed to remain at least 200 feet from other helicopters.

Helicopters performing air taxiing operations (normally not above 10 feet) on the movement area are considered to be taxiing aircraft.

Departing Aircraft

Taxi information issued to departing aircraft is listed in chapter 10 of this training manual.

Pilots of departing aircraft will contact ground control prior to taxi for taxi information. Formation leaders may request and receive taxi information for their entire flight.

Ground control issues the necessary instructions, and clears an aircraft from the parking area to the warmup area. Pilots of taxiing aircraft should remain on ground control frequency while in the warmup area until instructed to

AC.155

Figure 11-21.—Separation of a departing helicopter. (A) From a preceding departure; (B) from a preceding arrival.

Figure 11-22.—Separation of an arriving helicopter from a preceding arrival.

AC.157

Figure 11-23.—Separation of an arriving helicopter from a preceding departure.

change frequency by the ground controller, or until ready for takeoff clearance.

Because of critical fuel requirements in turbojet operations, there is a need for determining delays to departing turbojet aircraft for relay to pilots prior to engine start. Basically the procedure consists of the following:

1. The pilot contacts ground control before starting engines.

2. Ground control coordinates with ARTCC to determine any delay in receipt of en route IFR clearance.

3. If the delay does not exceed 15 minutes, inform the pilot NO DELAY EXPECTED.

4. If the delay exceeds 15 minutes, use the following procedure:

a. Inform the pilot of the proposed departure time.

10631 10630

as local traffic conditions permit. The facility must be informed of the VFR departure time.

Official ceiling and visibility are issued to departing VFR flights prior to takeoff when the weather is below VFR minimums; and to departing IFR flights when the weather is below takeoff minimums, or if none are established, when the weather is below VFR minimums.

The Navy has established takeoff minimums for IFR flights based on the pilot's instrument rating. These ratings are entitled Special or Standard and are issued to individual pilots after successful completion of a flight check and written exam administered by an Instrument Flight Board which is established by the Commanding Officer of a facility. There are no takeoff minimums established for pilots with a Special instrument rating and takeoff will depend on the judgment of the pilot and urgency of the flight. Takeoff may be authorized for pilots with a Standard instrument rating under the following conditions:

1. Where GCA is available, if the weather is at least ceiling 200 feet and visibility 1/2 mile, but in no case when the weather is below GCA minimums.

2. Where GCA is not available, if the weather is ceiling 300 feet and visibility 1 mile.

At certain air stations where commercial or air carrier aircraft are authorized to operate carrying passengers or cargo for hire or compensation, there is a minimum visibility below which takeoff clearance to such aircraft must be denied. The specific minimum visibility is variable, depending upon the type of visibility reporting procedure and equipment available at the particular station. Should your station be so affected, refer to the appropriate section of TATC Handbook 7110.8 (Series) for the applicable minimum visibility.

A departing IFR flight should be instructed to contact departure control when appropriate. For aircraft that can change radio frequencies after takeoff, the instructions are normally issued when the aircraft is one-half mile beyond the end of the runway provided that no further communications with the tower are required. For others, the instructions may be issued prior to, or in conjunction with, the takeoff clearance.

Takeoff clearance need not be withheld until prescribed separation exists if there is reasonable assurance that it will exist when the aircraft starts its takeoff roll.

Arriving Aircraft

Landing information, as appropriate, to be issued to arriving aircraft is listed in chapter 10 of this training manual.

A continuous broadcast of recorded non-control landing information is being used at certain high activity terminal areas. This service is called Automatic Terminal Information Service (ATIS). Its purpose is to relieve frequency congestion and improve controller effectiveness by eliminating the necessity of issuing routine essential information to each arrival. Pilots tune to the published frequency for the information. When they call the tower for landing instructions they indicate by some suitable phrase that they have the information and the controller only has to issue the necessary additional instructions.

At certain facilities, procedures may be established for arriving VFR traffic to contact approach control for landing and traffic information. In such cases approach control assists the local controller with the communications workload and traffic spacing in addition to enhancement of safety by making traffic information available for a greater distance from the airport. Local instruction will be promulgated which govern such operations.

Arriving aircraft normally call the tower for landing instructions prior to entering the airport traffic area. Aircraft carrying very important persons (VIP), or cargo requiring assistance, should contact the tower as soon as possible and again when entering the airport traffic area.

Spacing of arriving aircraft must begin prior to their reaching that portion of the traffic pattern where a landing clearance must be given. VFR traffic tends to arrive at irregular intervals or in large numbers requiring a controller to issue the necessary instructions and information to establish an evenly timed flow of traffic.

Traffic patterns are established at airports to specify the desired flow of air traffic in the vicinity of the airport. Standard patterns are left-hand patterns as depicted in figure 11-25. A conventional pattern, used mostly by reciprocating engine powered aircraft, consists of the following:

1. Upwind leg. A flight course parallel to the landing runway in the direction of landing.

2. Crosswind leg. A flight course at right angles to the landing runway off its upwind leg.

10633 scan

3. Downwind leg. A flight course parallel to the landing runway in the direction opposite to landing.

4. Base leg. A flight course at right angles to the landing runway off its approach end and extending from the downwind leg to the intersection of the runway centerline extended.

5. Final approach. A flight course in the direction of landing along the runway centerline extended from the base leg down to the runway. (See fig. 11-25.)

A standard overhead approach pattern for use by military high performance aircraft consists of the following:

1. An initial approach 3 to 5 miles in length.
2. A breakpoint at which the first 180 degree turn is started. (Normally over the numbers on the runway of intended landing.)
3. Direction of turns is normally left.
4. Pattern altitudes at least 500 feet above the conventional pattern until the second 180 degree turn is started.
5. A rollout on final approach not less than one-fourth mile from the runway threshold and not less than 300 feet above the ground. (See fig. 11-25.)

Entry of the overhead approach pattern is normally from the initial point. Entry of the conventional pattern is normally an interception of the downwind leg at an angle of 45 degrees. (See fig. 11-25.)

Specified procedures and control techniques vary from one facility to another, as well as from one controller to another. However, certain basic rules apply regardless of the techniques that are used; for example:

1. The controller is responsible for issuing instructions and information relative to all known traffic conditions.
2. All turns by the pilot around the airport will be left-hand, unless otherwise specified by the controller.
3. At least one component of a traffic pattern (final approach) will be used by the pilot, consistent with instructions issued by the controller.
4. Pilots are responsible for conformance with the applicable pattern requirements established by antinoise programs, etc.
5. Pilots have the final authority for the acceptance of clearances issued from the tower.

AC.159

Figure 11-25.—Conventional and overhead approach traffic patterns.

10634

6. All instructions issued by the controller, and accepted by the pilot, must be adhered to by the pilot concerned.

7. Pilots landing or taking off are entitled to all usable and available portions of the runway.

If it is necessary to hold arriving VFR aircraft at visual holding points because of traffic congestion, such aircraft would be cleared to a selected, prominent geographical fix easily recognized from the air and preferably one depicted on aeronautical charts. Instructions should be issued regarding the direction of holding and turns. Traffic information is issued to aircraft cleared to hold at the same fix.

Landing clearance is normally issued when arriving aircraft turn to base leg or begin the second 180 degree turn for the overhead approach. Such clearance is normally issued after prescribed separation between aircraft concerned exists and the pilot reports "wheels down."

Landing clearance need not be withheld until prescribed separation exists if there is reasonable assurance that it will exist when the aircraft crosses the landing threshold. However, a succeeding aircraft should not be cleared to land before a preceding arriving aircraft crosses the landing threshold.

Landing clearance may be issued to a radar-controlled aircraft when it is 3 miles from touchdown or landing threshold even though the preceding aircraft has not crossed the landing threshold provided that there is reasonable assurance that appropriate separation will exist when the radar-controlled aircraft crosses the threshold. Traffic information should be included with the landing clearance.

A landing clearance may not be withheld indefinitely, even though it appears a violation has been committed. The apparent violation might be the result of an emergency situation. In any event, assist the pilot to the maximum extent possible.

If the pilot of an aircraft requests clearance for an operation from a closed or unsafe runway, he should be advised of the runway condition. If the pilot persists in his request, a controller may quote the applicable parts of the NOTAM concerning the runway and inform the pilot that a clearance cannot be issued. Then if the pilot still insists and in the opinion of the controller the operation would not adversely affect other traffic, he should be informed that the operation will be at his own risk.

Ordnance, Parking, and Refueling Operations

When appropriate, the local controller may instruct the pilot where to turn off the runway after landing. This may be necessary for pilots who are unfamiliar with the field in order to expedite traffic; or special circumstances may require additional instructions to be issued such as to direct an aircraft to a dearming area.

At certain stations where flights require the use of ordnance, it may be necessary to direct aircraft to a particular arming/dearming area where ground crews can place the ordnance in a ready condition or render it harmless, as applicable. Where such operations are required, local authority establishes arming/dearming areas for each available runway. These areas vary at each station, but generally will be located in close proximity to the end of a usable runway and a specific heading will be determined upon which subject aircraft must be established before ordnance can be armed or dearmed. The required heading will be one that points the aircraft in a direction which is unpopulated or a clear area for safety purposes. These areas are interchangeably described as arming or dearming areas.

An arming area would be for use by aircraft just prior to takeoff and would be relatively close to the approach end of the runway. A dearming area would be one located near the upwind end of the runway for use by aircraft to be dearmed after they have completed their landing rollout. If the wind direction should shift 180° and the traffic pattern be reversed on this same runway, the description and the use of these areas would also be reversed.

Aircraft returning with hung ordnance, such as bombs that did not release, rockets that did not fire, etc., must be given special consideration by controllers to allow the pilot to avoid populated areas during his approach and insure that all other traffic is clear before landing clearance is issued. Generally, aircraft returning with hung ordnance are considered an emergency to expedite clearing the approach and landing area of other traffic.

NOTE: For more information on arming/dearming areas and procedures, refer to your local Air Operations Manual.

Pilots of arriving aircraft will normally shift to ground control frequency upon clearing the duty runway. At this time the ground

10635 10635

controller will issue any additional instructions necessary for the aircraft to proceed to the appropriate destination on the field. Pilots of aircraft based aboard a particular station or those who are known to be familiar with the field may only need an acknowledgment from ground control that they are on ground control frequency and a brief instruction to complete the operation.

EXAMPLE: TAXI TO YOUR LINE.

Pilots who are unfamiliar with the field may need precise step-by-step instruction to get the aircraft to the proper place. Actual parking of the aircraft is accomplished by a line crew; however, the ground controller should provide the line crew with advance notification of the aircraft arrival so that the transition from instructions issued by the tower to visual signals provided by the lineman is a smooth and continuous operation. Use of FOLLOW ME vehicles is common at many fields to simplify the procedure of getting an unfamiliar pilot to his destination on the field as expeditiously as possible. The ground controller will have communications with both the FOLLOW ME vehicle and the aircraft, but communications do not normally exist between the vehicle and the aircraft. This requires liaison and coordination to get the vehicle in the proper pickup position and insure that the pilot establishes visual contact with the vehicle. These vehicles are usually lighted for night use.

Refueling operations are outside the authority or responsibility of tower controllers; however, they may be called upon to relay advance information to the appropriate personnel about the type or grade of fuel required by a transient aircraft. This allows the refueling truck to be called out and meet such aircraft when they are parked, thereby expediting refueling and reducing ground time.

Priority

Air traffic control service is provided on a first come, first serve basis as circumstances permit, with the following exceptions:

1. Maximum possible priority should be provided military air evacuation flights when requested by a particular pilot. Particular consideration to priority should be given in terminal areas and to avoid turbulent conditions.
2. Maximum assistance should be provided SAR aircraft while performing a SAR mission.
3. Special handling may be required to expedite a Semiautomatic Flight Inspection Aircraft (SAFI), which is a specially equipped aircraft with a preplanned system of checking certain navigation aids.
4. Special consideration must be given to expedite the movement of the Presidential or the Vice Presidential aircraft and any escort aircraft as well as related control messages when traffic conditions and communications facilities permit.
5. Expeditious handling is required for any aircraft using the code name FLYNET. This code name indicates that the aircraft is transporting a nuclear emergency team to the location of a nuclear incident.
6. Expeditious handling must be provided to aircraft using the code name GARDEN PLOT when Central Altitude Reservation Facility (CARF) indicates that such priority is authorized. This code name is assigned to aircraft engaged in transporting troops to areas of civil unrest.

All naval air activities may assign priorities to VFR traffic. Priority is not normally given to VIP's; however, all Navy air traffic control facilities may give consideration to VIP's as long as safety is not affected.

The operation of jet-propelled aircraft necessitates expeditious handling to avoid excessive fuel consumption during taxiing, takeoff, and landing operations. Therefore, the following instructions must be followed by naval control tower operators:

1. Jet aircraft must NOT be granted priority for taxiing, takeoffs or landings unless the pilot so requests.
2. In granting priority: (1) Jet aircraft may be cleared first when propeller-driven aircraft will delay taxiing and takeoff; (2) if jet aircraft are ready for takeoff and propeller-driven aircraft are approaching for landing, jet aircraft may be cleared for takeoff and all other aircraft; except jet, hospital evacuation, and aircraft in emergency may be instructed to circle the field, (3) jet aircraft approaching for landing may be cleared ahead of all other aircraft (both jet and conventional) taking off and ahead of all other aircraft landing except those in emergency and hospital evacuation aircraft.

Pilots of jet aircraft should not request priority except when considered necessary. Ordinarily, the necessity should not exist for flights in local flying areas.

10838

VFR Helicopter Operations

Where helicopter and fixed wing aircraft use the same facility, a controller must consider the maneuverability and operational characteristics of helicopters when issuing instructions and information to establish a smooth flow of traffic. Helicopters do not necessarily conform to a standard traffic pattern as do fixed wing aircraft. Local procedures may be established to insure uniformity of helicopter operations. Local pilots would probably be familiar with such local procedures, but transient pilots would depend upon the controller to issue appropriate instructions. Conflicting flight paths and movements between helicopters and fixed wing aircraft must be prevented.

Pilots of helicopters should request permission from the control tower to cross a duty runway, or runway in use. The controller should then issue appropriate instructions based upon an assessment of the current traffic situation.

Navy helicopter flights within a control zone should not exceed an altitude of 500 feet unless authorized to do so by the control tower or other appropriate agency.

Helicopter training flights should stay well clear of other traffic. When they are within the boundaries of the airfield, the pilot should guard the tower frequency so a controller can keep the pilot informed of current traffic information.

Practice autorotations (defined in chapter 9) may be conducted within the limits of the field boundaries, over a surface where a full autorotation might be safely completed, and which is readily accessible to crash and firefighting equipment.

Special VFR Operations

Special VFR weather minimums are listed under FAR 91.107 in chapter 9 of this training manual.

Special VFR operations may be authorized only within control zones by the ATC facility providing IFR service to such control zones. This authorization is based on weather conditions officially reported at the airport of intended operations. If weather conditions are not reported at that airport, special VFR may be authorized whenever the pilot advises he is unable to maintain VFR and requests special VFR. (An example of such an airport would be a small outlying field that has no weather service available at the field.)

EXAMPLE: CLEARED OUT OF CONTROL ZONE NORTH OF PODUNK AIRPORT ON A HEADING OF THREE SIX ZERO, MAINTAIN SPECIAL VFR CONDITIONS WHILE IN CONTROL ZONE.

Local special VFR operations may be authorized for a specified period (such as a series of landings or takeoffs) upon request, if the aircraft can be recalled when traffic or weather conditions require. Where traffic density or complexity of operations warrant, Letters of Agreement may be consummated with the local authority.

Aircraft may be authorized to climb to VFR upon request if the only weather limitation is restricted visibility.

EXAMPLE: CLIMB TO VFR WITHIN THE THE CONTROL ZONE, MAINTAIN SPECIAL VFR CONDITIONS UNTIL REACHING VFR.

Approved separation must be provided between special VFR flights and between special VFR and IFR flights. One type of approved separation that is easily adaptable to special VFR operations is visual separation. (See chapter 12 of this training manual.) When applying vertical separation, a fixed altitude should not be assigned to a special VFR operation, but the special VFR aircraft may be cleared at or below an altitude which is at least 500 feet below any conflicting IFR traffic. Minimum safe altitudes must also be considered when applying this procedure.

CONTROL PROCEDURE. —For the purpose of the following discussion, these terms have the meanings indicated:

1. Ingress flight — An arriving aircraft which enters the control zone and lands at an airport within the zone.

2. Egress flight — A departing aircraft which takes off from an airport within the control zone and leaves the zone.

3. Local flight—An aircraft which operates within the traffic pattern of an airport within the control zone, usually for series of takeoffs and landings.

4. FW/SVFR—Fixed wing special VFR flights.

In control zones where FW/SVFR operations are permitted, priority may be given to arriving and departing IFR aircraft in accordance with the following:

1. Ingress or egress FW/SVFR flights are handled as follows:

a. Where radar service is provided by a terminal facility, ingress or egress FW/SVFR

flights may be authorized when arriving or departing IFR aircraft are within the control zone, provided:

(1) Arriving or departing IFR aircraft are not delayed.

(2) Radar surveillance of the FW/SVFR aircraft and the pertinent arriving or departing IFR aircraft is maintained until the FW/SVFR aircraft landing is assured or it has left the control zone.

b. When authorization cannot be granted for a FW/SVFR flight, the aircraft should be informed of the anticipated delay. If the aircraft is arriving, it should be instructed to remain outside the control zone. EAC's or EFC's are not issued to special VFR flights.

2. Local FW/SVFR flights should be handled as follows:

a. Where radar service is provided by a terminal facility, local FW/SVFR flights may be authorized when arriving or departing IFR aircraft are within the control zone, provided:

(1) Arriving or departing IFR aircraft are not delayed.

(2) Local FW/SVFR flights can be conducted independently and without conflict with arriving or departing IFR aircraft.

(3) Radar surveillance of arriving or departing IFR aircraft is maintained to insure that the flight paths of these aircraft do not encroach upon the area in which the local FW/SVFR flights are being conducted.

The priority afforded IFR aircraft over FW/SVFR aircraft is not intended to be so rigidly applied that it causes grossly inefficient use of airspace. If better overall efficiency will be gained thereby, the controller has the prerogative of allowing completion of a FW/SVFR operation already in progress when an IFR aircraft becomes a factor. Examples follow:

1. A FW/SVFR aircraft has been cleared to enter the control zone and subsequently an IFR aircraft is ready to depart or is in position to begin an approach. Less overall delay might accrue to the IFR aircraft if the FW/SVFR aircraft is allowed to proceed to the airport and land, rather than leave the control zone or be repositioned to provide IFR priority.

2. A FW/SVFR aircraft is number one for takeoff and located in such a position that the number two aircraft, an IFR flight, cannot taxi past to gain access to the runway. Less overall delay might accrue to the IFR aircraft by releasing the FW/SVFR departure rather than by having the aircraft taxi down the runway to a turnoff point so that the IFR aircraft could be released first.

At locations where radar service is provided by a center, or where radar service ordinarily provided by a terminal facility is out of commission or considered unsatisfactory radar coverage, FW/SVFR operations are authorized only when there are no IFR aircraft operating with the control zone.

Requests for authorization of special VFR operation within control zones, by other than helicopters, when the flight and/or ground visibility, as appropriate, is less than 1 mile must be treated as follows:

1. Pilots of departing aircraft who request such authorization must be advised of the weather conditions and that, as a result, such a clearance cannot be issued.

2. Pilots of aircraft who request clearance to enter a control zone and land must be advised of the weather conditions and that, as a result, unless an emergency situation exists, such a clearance cannot be issued.

3. Pilots of arriving aircraft operating within the control zone who request landing clearance must be advised that the ground visibility is less than 1 mile, and must be asked if the aircraft can depart the control zone with a flight visibility of at least 1 mile. If the aircraft cannot depart the control zone accordingly, or an emergency exists, issue a clearance as soon as traffic conditions permit.

When weather conditions are not officially reported at an airport and the pilot advises the flight visibility is less than 1 statute mile, treat requests for special VFR operations the same as outlined above except no mention need be made of the visibility since the pilot determines the extent of visibility in such cases.

Scheduled air carrier aircraft in the U. S. may be authorized takeoff or landing where a local surface restriction to visibility is not less than one-half mile, provided that all turns after takeoff or before landing and all flight beyond 1 mile from the airport boundary can be accomplished above or outside the area of visibility

10638

Figure 15-4. —Free-running multivibrator.

fixed delay circuit delays the firing of the transmitter until the nonlinear portion of the range sweep is past. The output of the fixed delay is then fed to the modulator and range marker circuits simultaneously. Thus, the range-marker circuits are turned on at the time the transmitter fires, and turned off at the end of the range sweep time by a pulse from the range sweep circuits. The output of the range marker circuits is fed to the indicator in the form of evenly spaced pulses and appear as intensified range lines on the scope.

The trigger to the range sweep circuits may be either delayed or direct. If direct, the range sweep will start immediately; if delayed, the range sweep will start sometime after the transmitter is fired, delay time being equal to the output of the variable delay circuit.

The range sweep circuits provide the indicator with sweeps of various time duration (ranges). They also furnish trigger pulses to start and stop operation of the intensity gate circuit (for unblanking the indicator during sweep time only), and an output to the rangemarker circuits to turn the marker circuits off at the end of sweep time.

TRANSMITTER

The transmitter is a high powered, high frequency microwave oscillator. It is designed to operate around a predetermined frequency and to be fairly stable at this frequency. It operates during the pulse period and is then shut off for a comparatively long rest period. Its power, in the form of high frequency microwave oscillations, is delivered during the pulse time to the waveguide transmission system for delivery to the antenna, where it is then propagated into space.

The block diagram (fig. 15-5) is a simplified drawing and does not refer to any particular type of transmitter; however, it contains the elements found in a majority of airborne radar systems.

The technician should bear in mind that the various components discussed may be physically located in one unit or in several different units, depending on the type of installation.

Functional Operation

Referring to figure 15-5, the trigger shaper receives an input trigger from the system's synchronizer. As the name implies, the trigger is amplified and shaped into a sharp trigger pulse and fed to the next stage, a cathode follower. The cathode follower is used to match the high output impedance of the trigger shaper to the low input impedance of the pulse switch stage. The output from the cathode follower is applied to the control grid of the pulse switch. Before discussing the triggering action, the function of the power supply, charging diode, and pulse forming network are discussed.

The power supply furnishes the high voltage and supplies the energy which the pulse forming network (PFN) stores for release to the transmitter. The PFN, an open end artificial transmission line, stores this energy, and determines the width and shape of the pulse to the transmitter. The charging diode controls

Figure 15-5. —Radar transmitter (block diagram).

1061

restriction. The pilot is solely responsible for determining if the nature of the visibility restriction will permit such operation.

Special VFR Helicopter Operations

Due to their special flight characteristics, helicopters are an exception to the minimum of 1 mile visibility for special VFR operations within a control zone. However, the Navy has established additional minimums for Special VFR Navy helicopter operations of one mile forward flight visibility and ceiling 500 feet.

Special VFR helicopter operations are controlled by the same procedures prescribed for special VFR aircraft unless other procedures are contained in a Letter of Agreement.

At locations where the volume or complexity of helicopter operations warrant, a Letter of Agreement will specify the fact that special VFR helicopter flights are required to maintain visual reference to the surface and traffic patterns, routes, and reporting or holding fixes necessary to achieve appropriate separation. These minimums are listed in TATC Handbook 7110.8 (Series) which should be referred to by AC's at air stations where the above situation exists.

Simulated Flameout
(SFO) Procedures

Military turbojet aircraft may be authorized to make SFO maneuvers. Practice SFO approaches are authorized only for specific Navy aircraft. However, precautionary SFO approaches might be made by any aircraft when engine failure is considered possible.

A simulated flameout pattern consist of the following:

1. High Key, which is a position over the airport where the pilot begins to maneuver the aircraft to enter a high downwind leg. (Recommended altitude 5,500 to 15,000 MSL.)
2. Low Key, which is a position on high downwind leg just before turning on base leg. (Recommended altitude 3,500 to 10,000 MSL.)
3. Flameout Maneuvering Area, which is that airspace to be occupied by an aircraft conducing a SFO approach, which begins at high key, includes the low key, and ends at the end of the runway. (See fig. 11-26.)

AC.160
Figure 11-26.—Simulated flameout pattern.

Aerial Tow Target Operations

Aerial tow targets and related equipment are used in gunnery practice by ships and shore installations and in air-to-air firing exercises. Towing operations enable gunners to fire at targets that simulate moving aircraft in speed, shape, and maneuvers.

Most aerial tow targets presently employed are of the type that can be released, or trailed, behind the aircraft in flight and retracted when the mission is completed. These targets do not normally require any special consideration concerning airport traffic control. However, the possibility of a mechanical malfunction exists and a pilot may not be able to retract the target. In such cases the pilot may desire to make a low approach over the airport and drop the target in an area from which it could be retrieved. The local Air Operations Manual designates specific procedures and areas for dropping towed targets.

It should be kept in mind that an aircraft with a tow in the traffic pattern is a definite hazard and the Air Controlman has the responsibility of controlling traffic accordingly. This may require additional spacing of traffic or having other traffic vacate the traffic pattern until the tow drop is complete.

Field Carrier Landing Practice

Involvement of the Air Controlman in the procedures of field carrier landing practice (FCLP) stems from his position of control of aircraft at and around the airport. The extent to which he is called upon to exercise control and handle other aspects connected with FCLP is discussed in the following sections.

The landing safety officer (LSO) is an experienced carrier pilot, designated and trained by the Navy to assist and instruct pilots in carrier and field carrier landing techniques. The LSO has direct responsibility for the aircraft in the FCLP pattern. The tower retains overall control of the traffic, which means the control tower will issue instructions whenever there is danger present to the aircraft in the pattern. To effectively accomplish this, there must be close coordination between the tower and the LSO regarding any emergency action that may be necessary. In addition, tower operators can relay any information to the LSO pertaining to the aircraft in the pattern if it will result in safer operations. The only instructions other than those issued by the control tower during FCLP when a hazardous condition exists, are initial takeoff clearance and taxi instructions. All other instructions given to the pilots of aircraft conducting FCLP are given by the LSO.

Practicing of FCLP is the most hazardous routine operation conducted on the field. The tower operator must be constantly alert for any emergency while these operations are in progress. These emergencies may result from spins, stalls, and ground loops, due to the slow speed and low altitude of the aircraft in the pattern. While conducting FCLP, more than the normal amount of crash requipment is required to be available on the field because of the greater hazards involved. Station instructions designate the positioning of this equipment and the amount required.

Pilots receive an extensive training program at shore installations, preparing them for actual carrier landings prior to going aboard an aircraft carrier. Therefore, to approximate shipboard landing conditions, a runway is marked off in size and shape similar to the flight deck of an aircraft carrier. Landing area markings, discussed earlier in this chapter, sometimes serve as a simulated flight deck for FCLP. However, when it is impractical to conduct FCLP operations on the landing area marking, additional simulated flight deck markings are painted at appropriate locations on the runway. Lights are used to outline the runway for nighttime use. These may be either portable lights or smudge pots.

FCLP PATTERN.—The FCLP pattern is usually a touch-and-go pattern. This means that the aircraft is able to stay in the pattern and complete more approaches. When the aircraft takes off, the pilot will usually turn slightly to the right so as to leave the runway clear of turbulence. An aircraft entering turbulence from an aircraft ahead may have trouble recovering because of the low altitude, and a crash may result. The airspeeds used vary with the type of aircraft; however, it is normally not much above stalling speed. In their final approach, aircraft are controlled by the LSO. The LSO may, at his discretion, wave off an aircraft at any point in the landing approach. The pilot will land after completion of the required number of approaches, or when low on fuel. The control tower will then issue instructions to the pilot for taxiing back to the parking area.

An aircraft receiving a waveoff will remain in the pattern and will make its next approach in its regular sequence, with other aircraft still in the pattern.

Most facilities have a portable or permanently installed Fresnel lens for use with FCLP. This visual landing aid is the same as that used aboard ship and is illustrated in chapter 13 of this Rate Training Manual.

EMERGENCY AND CRASH PROCEDURES

The facilities for fighting fires and aiding personnel involved in crashes are a vital part of the airport equipment.

While flight operations are being conducted, commanding officers must insure that adequate firefighting, crash, rescue, and ambulence equipment is on hand. They must also see that the equipment is favorably located, adequately manned, and in efficient operating condition and that the crew is alerted. Only a minimum of equipment is required on the field during normal operations, but other crash and rescue equipments are held in readiness at all times.

All air stations maintain a current crash bill detailing the duties of those assigned the handling of such emergencies including control tower operators. Additionally, procedures are established for handling emergencies or accidents when the aircraft involved is carrying

10640

hazardous cargo. These instructions are normally separate from the crash bill because of their classified nature.

It is the primary responsibility of the control tower operator to observe closely all activities on the airfield and within the visible traffic pattern, and maintain radio communications with aircraft concerned. Normally the control tower operator will obtain initial information on an impending emergency or accident. Control tower personnel must speedily convey exact information to crash, firefighting, and rescue units so that prompt action by those units can be taken.

Primary Crash Alarm Intercommunications System

This system is a direct wired intercommunications system normally installed between the control tower, flight clearance dispatcher, crash shack, and ambulance fixed stations. Its purpose is to provide an immediate means of communication to primary emergency activities so they may notify all essential supporting activities.

Secondary Crash Alarm Intercommunication System

This system may operate through the regular telephone switchboard and may be activated from the control tower and the flight clearance desk. This system is referred to as the "crash phone." Telephone receivers on this system are installed as required at each facility. The following stations are suggested:

1. Crash stations.
2. Fire stations.
3. Hospital or Dispensary.
4. Fire chief.
5. Security office.
6. Aircraft maintenance.
7. Boathouse (if near water).
8. Commanding Officer.
9. Officer of the Day.

This system allows notification of all essential personnel and activities simultaneously by the flight clearance dispatcher without further interference with control tower duties.

Emergency Radio Communications Systems

Two radio networks are provided for the purpose of coordinating crash and firefighting activities. The primary network is referred to as the "crash network" which provides communications between the control tower and the necessary mobile units such as crash trucks and ambulances. The other network is a standby or spare in case of outage of the primary equipment. The secondary network is referred to as the "internal security network."

Responsibility

In the event of a crash or impending emergency, control tower personnel must convey exact information to the necessary units concerned and keep them advised of the status and pertinent details. They must notify all traffic on the field and in the air of the crash or emergency, and, at the direction of the operations officer or his authorized representative, close the field to traffic until free for normal operations.

When activating the crash phone system, give the following information:

1. Crash or emergency.
2. Location of crash (using the crash grid map).
3. Brief description, including type of aircraft.
4. Number of persons aboard.
5. Ordnance load, if known.

Aircraft crashes are usually described as to location by using a grid map system especially constructed for this purpose. (See fig. 11-27.) Sometimes it is desirable to construct two grid maps. One map is used for crashes on or near the airport and one is expanded to cover more area for off station crashes. In either case all crash vehicles, crashboats, and rescue aircraft must be supplied with copies of these maps to be able to interpret tower directions. Two examples in using this map are: Area THREE FOXTROT would include the approach end of runway 18 and SIX BRAVO would include the approach end of runway three.

There is a certain amount of excitement generated with the occurrence of an emergency or crash. However, since you are transmitting very vital information it is extremely important

10641 10641

AC.161

Figure 11-27.—Crash grid map.

that you be CORRECT, CONCISE, and CALM. Remember that you are talking to several people at one time and they must absorb the information that you are giving in order to take proper action.

Emergencies and crashes more distant from the field are usually handled by search and rescue facilities. The procedures for alerting search and rescue facilities are covered in chapter 3 of this rate training manual.

10342

Parachute Distress Signals

Parachutes worn by some aircrewmen are equipped with a small radio transmitter which automatically activates after ejection or bailout. These units will transmit a distinctive tone on 243.0 (guard frequency). Their purpose is to call attention to the emergency and to provide a signal that can be used for homing or fixing to locate the downed airman. In addition, some equipment used by Navy aircrewmen has a voice transmit-receive capability for use after the airman has reached the ground.

When an emergency parachute signal is heard, the following action must be taken:

1. Attempt to obtain a bearing of the signal with the DF.
2. Notify the DF net control.

NOTE: Each facility is located in a DF net, which is an area determined geographically, for the purpose of obtaining cross bearings of aircraft lost or with an emergency thereby providing a fix. Each net has one station designated as net control for the purpose of coordination.

3. Forward bearings and any other pertinent information to the DF net control.

Preventing Wheels-Up Landings

There are many and varied reasons for wheels-up landings. They range all the way from mechanical failure of the landing gear system, to forgetfulness on the part of the pilot.

In order to keep wheels-up landings at a minimum regardless of the cause, most naval air stations post a wheel watch at the approach end of the duty runway. This watch is normally provided with two LSO paddles or flags and a pyrotechnic flare pistol or a control switch to the wheels-up warning lights (discussed earlier in this chapter) where installed.

The duty of the wheel watch is to closely observe each aircraft approaching for a landing and if the landing wheels appear to be down and in place he signals a ROGER (arms extended parallel to the ground). A waveoff (signal not to land) is given to all aircraft not having landing gear extended (wave arms overhead to side).

At any time there is any doubt, the wheel watch gives a waveoff. If the aircraft continues, and it becomes apparent that the waveoff signal has not been observed pyrotechnic flares are fired or the wheels up warning lights are activated, if applicable.

Alert controllers can prevent many wheels-up landings by closely observing each aircraft in the final stages of the landing approach and giving timely warnings when appropriate. Binoculars are provided in all Navy control towers specifically for the purpose of checking landing gear on landing traffic.

EMERGENCY RECOVERY EQUIPMENT ASHORE

EMERGENCY CHAIN TYPE ARRESTING GEAR

The chain type emergency arresting gear uses the principle of dragging weight behind an aircraft to stop it. The weight in this instance is chain that has been positioned on the runway parallel to and approximately 1 foot inboard from the edges. Two cross deck pendants (cables stretched across the runway) attached to the ends of the chain permit aircraft (with tailhooks), in case of an emergency, to be arrested by the tailhook catching the cross deck pendant and dragging the chain until the aircraft comes to a stop.

The chain gear consists of two cross deck pendants, two lengths of chain, and the necessary equipment to tie the two together to make the arresting gear unit.

The operation of the chain gear is very simple. The aircraft catches one of the cross deck pendants with its tailhook, and at this time the shearpin is broken. This releases the pendant, which is now connected only to the chain. The chain is then towed down the runway by the aircraft. (See fig. 11-28.) This permits the transfer of the energy of the arrested aircraft to the chain. The arrangement of the chain causes it to pay out gradually, thus progressively increasing the weight pulled by the aircraft. The energy of the arrested aircraft is dissipated by the chain until the arrestment is completed. Then the aircraft is disengaged from the gear and the gear is restored for future use.

AIRCRAFT EMERGENCY ARRESTING GEAR (WATER SQUEEZER)

The aircraft emergency (water squeezer) arresting gear is designed as an emergency standby gear for arresting hook-equipped aircraft. Located on the runway, it is ready to save

10643

AC.162

Figure 11-28.—Operation of chain arresting gear.

the pilot and the aircraft in case of an aborted takeoff or an emergency overrun landing. (See fig. 11-29.)

The arresting gear is designed so that it can be installed quickly and easily with little obstruction to the runway. The general arrangement of the arresting gear is shown in figure 11-29. The manner in which each arresting gear is installed depends upon the local conditions and requirements.

It is designed to arrest hook-equipped aircraft up to 50,000 pounds in weight and at engaging speeds up to 160 knots. Within these limits the aircraft will be halted within a 1,000-foot runout. Engagements may safely be made at up to 50 feet to either side of the runway centerline. There is only one cross deck pendant, which spans the runway, and may be engaged by an aircraft landing in either direction. (See fig. 11-29.) The time required to rerig will depend entirely upon weather conditions and the number and experience of personnel assigned to the task. It should be possible, however, to complete the rerigging operation within 15 to 20 minutes, provided that no repairs are necessary. The time it takes to get this sytem ready for another engagement is much less than the time required for the chain type gear. This is a definite advantage.

ROTARY FRICTION ENGINE EMERGENCY ARRESTING GEAR

The purpose of the rotary friction engine arresting gear is the same as chain or water squeezer type, but is a later design to handle heavier and faster aircraft. Additionally it has a rerigging time of approximately 5 minutes.

The arresting engine consists of a nylon tape or tapes wound around a drum. The aircraft is stopped by unwinding the tape while a braking action is applied to the drum. There are various designations for the equipment to signify a difference in either the quantity of engines used, the installation configurations, or both. In other words, some installations have the engines installed in pits on each side of the runway, some have just one engine on one side of the runway with the tape passed under the runway to the other side of the deck. Other installations have the units installed above deck.

Aircraft arrestment with this type of gear is accomplished by the engagement of the aircraft arresting hook with a single cross deck pendant which spans the runway and can be engaged from either direction. During runout, the energy of the arrested aircraft is absorbed in the rotary friction arresting engine.

10644

AC.163

Figure 11-29.—Emergency arresting gear (water squeezer).

As the aircraft arresting hook engages the cross deck pendant, the tape storage reels turn and the tape pays out. This action causes the energy of the aircraft to be absorbed by the braking action of the arresting gear engine or engines.

The installation in figure 11-30 is an above deck installation and includes two arresting engines, one on each side of the runway. The engines are attached in parallel to one cross deck pendant. This configuration uses two nylon tapes on each engine attached to a single cross deck pendant. However, some above deck installations have only one tape per engine. The cross deck pendant is a cable 1 1/4 inches in diameter and the nylon tape has an ultimate strength of 65,000 pounds.

MOREST EMERGENCY ARRESTING GEAR

Morest arresting gear is a self-sustaining, mobile, portable unit that is capable of being installed on small landing fields. (See fig. 11-31.)

The arresting engines are mounted on a semi-trailer for mobility. In figure 11-31 the wheels have been removed from the trailer so the engines can be stabilized.

E-28 EMERGENCY RUNWAY ARRESTING GEAR

The E-28 arresting gear is a rotary hydraulic system. It is fast and efficient, and needs little maintenance. It can arrest hook equipped aircraft in all types of landings. The simplicity of the gear's structure, and its high caliber reliability, make it exceptional. The cycle time for reuse is approximately 80 seconds. No initial preparation or adjustments are necessary for arresting any type of naval aircraft. A man can usually qualify to operate the E-28 within a day or so. Figure 11-32 is an example of the E-28 installation. It is anticipated that the E-28 will replace all other types of arresting gear ashore eventually.

10645 ... 00301

AC.164

Figure 11-30.—Rotary friction engine emergency arresting gear.

Basically, the E-28 includes a rotary hydraulic system with two identical arresting engines that control the payout of a cross-deck pendant held by the nylon tapes that feed into a winding drum mechanism attached to each energy absorber unit. Each system also contains a cooling system and a retrieve system. Once the hook engages the pendant, the forward motion of the aircraft pulls out the nylon purchase tape and activates the energy absorber units. Each such unit has a rotor and an arrangement of stationary vanes in a container of hydraulic fluid. As the tape unwinds, the rotating wheel turns the rotor, thus creating turbulence in the fluid. This turbulent fluid offers such resistance against the rotor that the speed of the unwinding wheel reel diminishes to the point where the payout of tape is stopped. The heat generated by resistance of the turbulence is drawn off by the pumping of the hydraulic fluid through a cooling tank in which the large exposed surface serves as a heat exchanger, dissipating excess heat to the outside air. The retrieve assembly is a gasoline engine driven assembly with an electrical starting system and is operated from a control panel on the assembly base. The retrieve assembly rewinds the tape and pre-tensions the pendant after each arrest.

RUNWAY OVERRUN BARRIER

Barriers are that part of the shore based recovery equipment used for the emergency arrestment of aircraft which, because of tailhook or other mechanical failure, cannot make a normal arrested landing during an emergency situation. The makeup of the barrier includes the following basic items or parts: nylon webbing, port and starboard stanchions, and cross deck pendants that are attached to the arresting gear as previously described.

The barrier webbing assembly is a group of all nylon webbing, straps combined as a unit, through which the kinetic energy of an aircraft is absorbed, to produce arrestment within a short runout distance. (See fig. 11-33.)

When the aircraft engages the barrier, the nose penetrates the webbing and the vertical straps engage the leading edges of the wings and wrap about the aircraft. The barricade then

10646

AC.165

Figure 11-31.—Morest emergency arresting gear.

passes the forces of arrestment to the chain, water squeezer, or nylon tape, at which point the arresting procedure follows in the same manner as the three previously described emergency arresting techniques.

Whenever possible, the barrier is located in the runway overrun area at a sufficient distance from the end of the runway to permit it to remain in a ready position while conducting normal aircraft operations. If sufficient overrun area is not available for such installation, the barrier is located as close to the end of the runway as possible. However, locating the barrier so near the runway makes the barrier an obstruction hazard when making approaches over it. For this reason it is required that it be possible to raise and lower the barrier. At most installations, it can be controlled remotely from the tower.

Emergency recovery of an aircraft by the barrier is the least desirable system described in this chapter, since some damage to the aircraft is likely to result. However, damage is usually minor compared to what could result during an aborted takeoff or during a landing when the aircraft would roll past the runway or overrun area into rough surface where considerable damage and/or injury to occupants could occur.

LOCATION OF ARRESTING GEAR

Figure 11-34 shows possible locations of emergency arresting gear. Location A represents a runway overrun barrier for aborted takeoffs and landing overruns. Location B represents an installation where only one gear is available and affords landing protection in both directions, but does not provide for an aborted arrestment. Location C represents an installation that provides landing overrun and aborted takeoff protection for both ends of a runway where overrun areas are inadequate.

10647

AC.166

Figure 11-32.—E-28 emergency arresting gear.

RUNWAY FOAMING

Due to the numerous variables present in any emergency landing there is little chance of positively and accurately predicting the usefulness of foam in any given emergency. However, where there is likelihood of fuel spillage that may ignite from friction produced sparks, the use of foam on the runway will decrease the possibility of a fire from this source by a significant factor. Time is of the essence. First consideration is an estimate of how long the aircraft concerned can remain airborne. The crash trucks require a minimum of 10 to 20 minutes to apply a foam blanket, recharge, and return to the standby position.

The operations officer (operations duty officer) is responsible for the decision to foam the runway with or without pilot request if considered desirable, and conversely, to deny the procedure if necessary.

Foam Patterns

Presently there are two basic foam patterns used. They are as follows:

1. Foam is laid from the 2,000 foot to the 5,000 foot position in the center of the runway approximately 40 feet wide. This pattern is usually associated with the landing gear retracted or "belly landing."

2. Foam is laid immediately upwind of the arresting gear that is to be used. It extends for 1,500 feet and fans out toward the side in which the aircraft is anticipated to swerve.

Foam may be removed from the runway in one or two ways. During hours of sunshine, water will settle out of foam and evaporate readily in 2 or 3 hours, or small areas may be washed away with high pressure hose.

In any event, the runway may have reduced braking action until the foam is dry or is removed.

the transfer of energy from the power supply to the PFN. The use of an inductive charging impedance causes the PFN to charge to approximately twice the power supply voltage. It also prevents the power supply output from being shorted during the pulse time when the switch tube conducts.

The pulse switch, when triggered, acts like a closed switch which completes the circuit for discharge of the PFN very rapidly through the primary of the pulse transformer. The pulse transformer matches the impedance of the transmitter to the characteristic impedance of the PFN, and thus results in maximum power transfer. Also by using a step-up transformer (from the PFN to the transmitter), a lower voltage may be used on the PFN for a given pulse voltage to the transmitter.

A magnetron is used as the transmitting tube in most pulsed transmitters operation at frequencies above 1000 mc. The fact that the magnetron has the capability of high power outputs and is not subject to the change in input impedance at high frequencies encountered in conventional tubes, makes it well suited for use at these high frequencies. Several types of oscillators have been developed which compete with magnetrons as radar high-powered oscillators, such as the velocity modulated types, the back-wave oscillator, and the klystron, which operate in the radar range and are capable of greater power output than the triodes. These are discussed in chapter 12 of this course.

The magnetron, which is a self-excited oscillator, possesses fair frequency stability as compared with the more stable lower frequency oscillators (electron coupled or crystal controlled). However, the overall system will provide adequate stability when automatic frequency control (AFC) is used with the local oscillator.

As explained in Basic Electronics, NavPers 10087-B, the magnetron is a type of diode using and axiel magnetic field which is perpendicular to the electric field that exists between the cathode and the anode. This magnetic field is usually provided by a permanent magnet.

The tube consists of a cylindrical plate, with a cathode positioned coaxially inside it. The tuned circuits in which the oscillations take place are resonant cavities in the plate.

The duplexer, which consists of an ATR and a TR, is used to enable the use of one antenna for both the transmit and receive cycle of the system. The TR device effectively blocks the transmitter's energy from entering the receiver during transmit time—the ATR device insures that all reflected energy is directed to the receiver during receive time. The actual construction and operation of the TR and ATR devices are discussed later in this chapter.

Prior to the actual circuit analysis of a typical airborne radar transmitter, it is necessary that you first have an understanding of the various components used in conjunction with the transmitter, their uses, construction, and theory of operation.

ANTENNA SYSTEM

The antenna system has two general purposes. It radiates pulses of microwave energy developed by the magnetron, confining the waves into a narrow beam. In addition it receives the echo signals from targets which are applied to the receiver. The antenna system consists of waveguides, switching tubes, a reflector for beaming the radiated energy and concentrating the received energy, a mechanism for rotating the reflector during operation, and servo units which coordinate the position of the indicator sweep with the position of the antenna reflector.

Duplexers

In present day aviation radar, it is desirable to use a single antenna for both transmitting and receiving. A fast acting electronic switching device is required to disconnect the receiver from the transmission line during periods of transmission and to disconnect the magnetron during periods of reception. The receiver must be disconnected in order to protect the receiver input section and crystal since the magnetron output may be several megawatts. The magnetron must be disconnected during periods of reception in order to allow all available reflected energy from the target to pass to the receiver.

The duplexer is the device which performs this dual function of switching the antenna for transmitting and receiving, and protecting the

CHAPTER 12

IFR AIR TRAFFIC CONTROL

Controlling air traffic under IFR conditions is a demanding task. Controllers must be precise in their actions, considering the increased responsibilities as compared to VFR air traffic control. In the case of the latter, clearances and instructions were issued to assist the pilot in avoiding collision and to enhance the flow of air traffic. In comparison, clearances and instructions are issued to IFR traffic for the purpose of keeping all such traffic appropriately separated and at a safe altitude above terrain.

Navy AC's will most likely be involved with the control of IFR traffic at a terminal facility. However, there is a possibility that your terminal facility may operate in an en route capacity. Since you will be controlling IFR flights into and out of a terminal area, a basic knowledge of the entire airspace system is necessary.

As with any difficult procedure, the logical start is with basic details. The intent herein is to discuss IFR air traffic control procedure and minima so the AC3 or AC2 can describe them, and with the necessary supervised experience, apply them to the actual control of IFR air traffic.

NATIONAL AIRSPACE SYSTEM

The national airspace system as it exists today began to develop in 1918 with the U.S. Post Office airmail service. Radio equipment was installed near telephones, providing a link of air and ground communications for keeping track of air traffic.

Lighted airways were set up using rotating light beacons spaced at specific intervals by which pilots could navigate. Coded lights were later added to the rotating beacons so that pilots could determine their distance from a certain reference point with knowledge of the code. Low frequency radio range stations were established and became a government operated system for aircraft navigation when landmarks and lighted airways were obscured by clouds, etc. In striving for increased reliability and to meet increasing air traffic needs, several types of air navigation aids were developed and put into general use. Military technology added impetus to the drive to provide the best possible navigation aids for use within national airspace with contributions such as radar, IFF, and tactical air navigation (TACAN).

The Federal Aviation Act of 1958 established the Federal Aviation Administration (FAA) which is charged by Congress with the safe and efficient use of airspace of the U.S. This includes military aircraft operations within the U.S. airspace, hence the required compliance of Navy AC's with air traffic rules and regulations of the FAA.

Two route systems have been established for air navigational purposes within the contiguous U.S.—the airway system and the jet route system. The airway system consists of airways designated from not less than 700 feet above the surface, up to but not including 18,000 feet MSL, and is designed to serve aircraft which operate at these altitudes. They are predicated solely on VOR/VORTAC navaids. They are designated on aeronautical charts by a V and referred to orally as Victor airways. The jet route system consists of jet routes established from 18,000 feet MSL to FL 450 inclusive, and are designed to serve aircraft which operate at these altitudes. They are identified by a J on aeronautical charts and referred to orally by statement of the same letter.

The airspace structure above FL 450 is designed to permit free selection of routes. Navigation is conducted by navaids serving the jet route system provided the aids are not more than 200 miles apart. Flight above FL 600 must contain at least one fix within each ARTCC's area through which flight is planned without regard to distance between fixes.

10651

IFR air traffic control service is provided within controlled airspace. This controlled airspace includes airways, jet routes, control areas, transition areas, control zones, and the continental control area. These areas are described in chapter 9 of this training manual.

Airspace of the contiguous U.S. from FL 240 to FL 600 inclusive, except an area roughly described as the northeast 1/4th of the U.S. within which the effective limits are from 18,000 feet MSL to FL 600 inclusive, is designated as positive controlled airspace. Positive control of all air traffic within this area is exercised and additional requirements for flight apply as follows:

1. Complete IFR flight procedure is required and prior ATC approval mandatory.

2. All aircraft must be equipped with a coded radar beacon transponder (discussed in chapter 13), having a Mode 3, 64-Code capability which must be operated to reply to Mode 3 interrogation with the code specified by ATC, provided that in the event a radar beacon transponder failure is experienced in flight, ATC may approve operation within positive control area.

3. All aircraft must be equipped with radio equipment capable of providing direct pilot-controller communications on the frequencies specified by ATC for the sector in which flight is conducted. Pilots will monitor assigned ATC frequency and request ATC permission prior to any change. This includes aircraft in formation and those operating in altitude reservations.

4. Local flying areas are established within the positive control area to permit activities which are not readily adaptable to air traffic control. This includes activities in which aircraft do not maintain constant heading and/or altitude; that is, local areas are not restricted areas but are open to any user, traffic permitting. ATC clearance is required and aircraft are assigned to a flight level or group of levels by ATC, depending on the activity. Using military activities may schedule aircraft to operate in local flying areas in excess of the quantities that can be accepted by ATC, subject to Military Assumption of Responsibility for Separation of Aircraft. In this event, participating aircraft must remain in VFR conditions to preclude collision with other aircraft in the local areas.

5. Radius of action flight plans may be approved consistent with traffic conditions. However, pilots should be prepared to convert to point-to-point routing should radius clearance be refused.

6. Altitude reservations continue to apply within the positive control areas.

Procedures for entering and departing positive control areas are as follows:

1. Pilots operating on IFR flight at an assigned flight level require no additional clearance.

2. Pilots operating VFR and VFR on top (on IFR flight plan) must obtain an ATC clearance with an assigned flight level prior to entering positive control areas. An abbreviated flight plan containing the following information must be provided ATC at least 30 minutes prior to estimated penetration:

a. Identification
b. True airspeed (TAS)
c. VFR position and altitude/flight level
d. Estimated time and point of penetration
e. Requested route and flight level

3. When flight inbound to destination is VFR on top above the positive control area or departure from the area is to be IFR/VFR on top, only the discrete frequency of the sector of arrival or departure need be preset.

4. Upon departing the area, IFF/SIF is reset to the proper Mode 3 Code as assigned by ATC.

IFR CONTROL PROCEDURE

The procedure and minima which apply when providing IFR air traffic control service are those contained in Terminal Air Traffic Control Handbook 7110.8 (Series). When other procedures are contained in a Letter of Agreement, or other appropriate FAA or military document, they may only supplement the TATC Handbook 7110.8. Any minima they specify cannot be less than those in TATC Handbook 7110.8 unless appropriate military authority has authorized application of reduced separation between military aircraft in special procedures. The ultimate authority for naval ATC procedures is CNO. Deviation is also permitted when necessary to conform with pertinent ICAO Documents, National Rules of the Air, or special agreements in airspace outside the U.S. and its possessions where the U.S. provides air traffic control service.

Military procedures in the form of additions, modifications, and exceptions to the basic FAA procedure are provided in TATC Handbook 7110.8 when a common procedure has not been attained or to fulfill a specific requirement. These military procedures are applied by ATC facilities operated by the designated military service, by ATC facilities supporting a designated military service exclusively, or by other ATC facilities when specified in a Letter of Agreement.

IFR CONTROL RESPONSIBILITY

Air Route Traffic Control Centers (ARTCC's) provide air traffic control service to IFR and special VFR aircraft operating within controlled airspace except where this responsibility has been delegated to another facility.

Other facilities, such as approach control or a RATCC, provide air traffic control service to IFR and special VFR aircraft for which control responsibility has been received.

PRIORITY OF SERVICE

First priority is given to the separation of aircraft to comply with the procedure and minima prescribed for the control of IFR traffic. Any other service or information is provided to the extent possible.

Radar procedures should be used in preference to nonradar procedures to the extent practicable, consistent with workload, communications, and equipment capabilities.

Air traffic control service is provided on a "first come, first serve" basis as circumstances allow. For example, it is solely the pilot's prerogative to cancel his IFR flight plan, but a retention of an IFR flight plan does not afford priority over VFR aircraft, and he may be required to adjust his flightpath to enter a traffic pattern in sequence with arriving VFR aircraft. Exceptions to the first come, first serve rule do exist for certain types of aircraft operations such as AIREVAC, SAFI, Presidential and Vice Presidential, FLYNET, and GARDEN PLOT aircraft. For more information on this subject, see Priority in chapter 11 of this training manual and the appropriate section of TATC Handbook 7110.8.

TRANSFER OF IFR CONTROL RESPONSIBILITY

Control responsibility must be transferred between facilities, or between controllers within a facility, at a specified time, fix, or altitude. Additionally, any potential conflict with other aircraft under the jurisdiction of the transferring facility or controller must be eliminated prior to the transfer of control responsibility.

TRANSFER OF RADIO COMMUNICATIONS

Radio communications are transferred by specifying to the aircraft the following:

1. Location name of the facility or the terminal control function to be contacted. (The location name may be omitted when transferring communications within the same terminal area facility.)
2. Frequency to use. (When departure control frequency has been previously issued, omit the frequency.)
3. The time, fix, altitude, or specified conditions to contact the receiving facility. (This may also be omitted when transferring communications within the same terminal area facility.)

EXAMPLE: CONTACT KEYWEST APPROACH CONTROL TWO SIX THREE POINT SIX LEAVING FLIGHT LEVEL TWO ZERO ZERO; or, CONTACT DEPARTURE CONTROL WHEN AIRBORNE.

FORMATION FLIGHTS

Formation flights are treated as single aircraft unless the formation leader requests that ATC separate individual aircraft.

IFR CLEARANCE DELIVERY AND RELAY

IFR clearances issued by a facility other than the originating facility must be relayed verbatim. A non-ATC facility would prefix the clearance with the prefatory phrase "ATC clears." Such facilities would handle a relay of advice or a request for information in the same manner; i.e., "ATC advises," or "ATC requests." When a clearance, information, or a request for information is issued to an ATC facility or to an aircraft by direct ATC communications, the "ATC" portion of the prefatory phrase is omitted.

To correctly apply this procedure, refer to the definition of an ATC facility and ATC service. These definitions are included in appendix I of this training manual.

10653

When appropriate, specific delivery instructions may be issued with a clearance for relay, such as an "attempt delivery" time or a "cancellation" time which must be adhered to by the relaying facility. The ATC facility originating the clearance should be advised if the requirements of specific delivery instructions are not met.

SIGNIFICANT WEATHER

Every assistance should be afforded pilots to enable them to avoid areas of significant weather. When a requested deviation to avoid such areas cannot be approved due to traffic conditions, the altitude or route of the conflicting traffic may be changed to permit approval if there is reasonable assurance that the action will not place the conflicting aircraft in hazardous weather conditions.

Pilot reported information about significant weather conditions should be relayed to other aircraft concerned and the appropriate weather service.

ALTIMETER SETTING INFORMATION

Altimeter settings issued to IFR flights must be current settings obtained from direct-reading instruments or received directly from weather reporting stations.

When issuing an altimeter setting to an aircraft, a terminal facility must identify the source of the setting for a location other than at the facility. The time of the report must also be included if it is more than 1 hour old.

Aircraft operating below flight level 180 must be issued the associated altimeter setting of compulsory reporting points when reporting over such points. If in "radar contact", the controller issues the altimeter setting when the aircraft is observed passing or adjacent to compulsory reporting points. (Pilots discontinue making position reports when informed of "radar contact.")

When aircraft have been cleared to descend from a flight level to an altitude below the lowest usable flight level, the altimeter setting for the weather reporting station nearest the aircraft's position must be issued to the pilot.

The destination altimeter setting should be issued to pilot's of arriving aircraft when they are approximately 50 miles from destination unless approach control service will be provided; or it may be issued even though approach control service will be provided. (Approach control issues the altimeter setting on initial contact.) It is not necessary to issue additional altimeter settings when such aircraft report over subsequent compulsory reporting points since the destination altimeter setting is the one upon which the approach is predicated.

ALTITUDE VERIFICATION

If the pilot of an IFR aircraft does not provide altitude information on initial contact and with each position report, he should be requested to verify altitude information.

EXAMPLE: VERIFY AT FIVE THOUSAND.

Terminal area facilities should apply this procedure on initial contact after receiving control jurisdiction from another facility or when communications are established with an aircraft departing from another airport under their control jurisdiction. However, it is not necessary to verify altitude when, on initial contact, a new altitude is assigned an aircraft that is climbing or descending.

NONRECEIPT OF POSITION REPORTS

When a position report affecting separation is not received, action should be taken to obtain the report not later than 5 minutes after the aircraft was estimated over the fix.

NONRADAR IFR SEPARATION MINIMUMS AND METHODS

Pilots are required to file IFR flight plans and obtain an ATC clearance prior to conducting flight under instrument flight rules of FAR 91 within controlled airspace. Special VFR flights must obtain an ATC clearance prior to operations within control zones. By this procedure, ATC facilities know of all IFR and special VFR traffic operating within controlled airspace for which they are responsible. Thus they are able to regulate traffic by issuance of clearances and instructions for the purpose of keeping such traffic separated.

There are three types of nonradar separation: vertical, longitudinal, and lateral. One of these must be in effect whenever separation is required. Exceptions to the above statement are instances when controllers or pilots are authorized to maintain visual separation between

10654

aircraft, or when pilots are authorized upon request to operate IFR in accordance with a VFR restriction (discussed later in this chapter).

Each type of nonradar separation has established minimums to which controllers must adhere for safe operation. These minimums and methods of establishing and maintaining them are discussed separately in this chapter.

Vertical Separation

IFR aircraft may be separated vertically by assigning different altitudes or flight levels (FL), using the following minimums:

1. Up to and including FL 290-1,000 feet.
2. Above FL 290-2,000 feet.

A previously occupied altitude/FL may be reassigned to another aircraft when the pilot of the aircraft that previously occupied the altitude reports leaving it. However, when severe turbulence is reported, such altitudes may not be reassigned until the pilot of the aircraft that previously occupied the altitude reports at or passing another altitude separated from the first by appropriate minimum vertical separation.

EXAMPLE OF PHRASEOLOGY: REPORT LEAVING/REACHING FIVE THOUSAND; or, REPORT LEAVING ODD ALTITUDES; or SAY YOUR ALTITUDE.

When pilots of aircraft in direct radio communication with each other during climb and descent concur, the lower aircraft, if climbing, or upper aircraft, if descending, may be authorized to maintain their own vertical separation.

Longitudinal Separation

Longitudinal separation is spacing of aircraft so that after one aircraft passes over a specific position, a succeeding aircraft occupying the same altitude will not arrive over that position with less than the minimum longitudinal separation prescribed for the particular situation.

Longitudinal separation may be established by requiring aircraft to do one of the following:

1. Depart at a specified time.
2. Arrive at a fix at a specified time.
3. Hold at a fix until a specified time.
4. Change altitude at a specified time or fix.

DME procedures and minimums may only be used when direct pilot-controller communications are maintained.

Aircraft on the same, converging, or crossing courses at the same altitude are separated by an interval expressed in minutes of flying time or a specified distance in accordance with the following minimums:

1. When a leading aircraft maintains a speed at least 44 knots faster than a following aircraft, and (a) a departing aircraft follows a preceding aircraft which has taken off from the same or adjacent airport, or (b) a departing aircraft follows a preceding en route aircraft which has reported over a fix serving the departure airport, the minimum is 5 miles between aircraft using DME or 3 minutes between other aircraft. (See fig. 12-1.)

2. When a leading aircraft maintains a speed of at least 22 knots faster than a following aircraft, and (a) a departing aircraft follows a preceding aircraft which has taken off from the same or an adjacent airport, or (b) a departing aircraft follows a preceding en route aircraft which has reported over a fix serving the departure airport, or (c) an en route aircraft follows a preceding en route aircraft which has reported over the same fix, the minimum is 10 miles between aircraft using DME or 5 minutes between other aircraft. (See fig. 12-2.)

3. Minimum separation between aircraft climbing or descending through the altitude of another aircraft is as follows:

a. 10 miles between aircraft using DME, provided that the descending aircraft is leading or the climbing aircraft is following. (See fig. 12-3.)

b. 5 minutes between other aircraft if all of the following conditions are met:

(1) The descending aircraft is leading or the climbing aircraft is following. (Up behind/down in front.)

(2) The aircraft were separated by not more than 4,000 feet when the altitude change started.

(3) The change is started within 10 minutes after a following aircraft reports over a fix reported over by the leading aircraft or has acknowledged a clearance specifying the time to cross the same fix. (See fig. 12-4.)

4. If the required conditions which allow 3-minute/5-mile or 5-minute/10-mile separation for aircraft assigned the same altitude or 5-minute/10-mile separation for same direction aircraft climbing or descending do not exist, then the minimum longitudinal separation is 20 miles between aircraft using DME or 10 minutes between other aircraft.

AC.169

Figure 12-1.—5-mile or 3-minute longitudinal separation.

5. The minimum between an aircraft using DME and an aircraft not using DME is 30 miles if both of the following conditions are met:

a. The aircraft using DME derives distance information by reference to the same navaid over which the aircraft not using DME has reported.

10656

AC.170

Figure 12-2.—10-mile or 5-minute longitudinal separation

b. The aircraft not using DME is within 15 minutes of the navaid. (See fig. 12-5.)

Opposite direction traffic requesting a conflicting altitude change must be separated by minimum vertical separation from 10 minutes before until 10 minutes after they estimated to pass. (See fig. 12-6.)

Vertical separation may be discontinued after one of the following conditions is met:

1. Both aircraft have reported passing navaids or DME fixes indicating they have passed each other.

2. Both aircraft have reported passing the same intersection and they are at least 3 minutes apart.

When pilots of aircraft on the same course and in direct communication with each other

AC.171

Figure 12-3.—Same direction altitude change using DME.

10657
08801

AC.172

Figure 12-4.—Same direction altitude change.

concur, the pilot of the following aircraft may be authorized to maintain longitudinal separation of 10 minutes, or 20 miles if they are using DME, from the leading aircraft.

Lateral Separation

Lateral separation is the lateral spacing of aircraft at the same altitude. Aircraft may be laterally separated by one of the following methods:

1. Clear aircraft on different airways or routes whose airspace to be protected for one flight does not overlap airspace to be protected for the other. NOTE: Airspace protected for airways and routes is based on the width described in FAR 71.5 which is normally 4 miles either side of centerline.

2. Clear aircraft below 18,000 to proceed to and report over or hold at different geographical locations determined visually or by reference to navaids. (See fig. 12-7.)

3. Clear aircraft to hold over different fixes whose holding pattern airspace areas do not overlap each other or other airspace to be protected.

4. Clear departing aircraft to fly specified headings which diverge by at least 45 degrees. (See fig. 12-7.)

Lateral separation is considered to exist between aircraft established on radials of the same navaid that diverge by at least 15 degrees when either aircraft is beyond the airspace to be protected for the other aircraft. (See fig. 12-8.)

There is a table in TATC Handbook 7110.8 under the lateral separation section that shows appropriate distances necessary to clear the airspace to be protected for divergence angles from 15 to 90 degrees. Since this type computation is one which should be predetermined and shown on charts located at or near operating positions rather than an on the spot type separation, the table is not included herein.

Lateral DME separation is applied by requiring aircraft using DME to fly an arc or arcs of a navigational aid.

The minimum is 10 miles between arcs of a navigational aid when aircraft are maintaining different specified arcs of the aid.

Between an arc of a navigational aid and the boundary of the holding pattern airspace to be protected for an aircraft holding the minimum is 5 miles. (See fig. 12-9.)

Airspace to be protected along other than established airways or routes is as follows:

1. For direct courses and course changes of 15 degrees or less at FL 600 and below, and any course change below FL 180, the width of the protected airspace is 4 miles on each side of the route to a point 51 miles from a navaid. Beyond the 51-mile point, the airspace increases in width, based on a 4.5-degree angle from the aid, to a width of 10 miles on each side of the route at a distance of 130 miles. (See fig. 12-10.)

2. For course changes of more than 15 degrees through 90 degrees, the airspace to be protected on the overflown side, beginning at a point where the course change begins, is as follows:

a. FL 180 to FL 230 inclusive—14 miles.

b. Above FL 230 to FL 600 inclusive—17 miles.

3. For course changes of more than 90 degrees through 180 degrees, the airspace to

10658

receiver against the high power pulse from the transmitter. In addition, there is one device which is sometimes used in conjunction with the duplexer which should be mentioned at this time, although it is not a true duplexer.

A CRYSTAL SHUTTER is frequently used as a protective device for the receiver crystal while the radar is turned off, due to the possibility that energy radiated from nearby radars may damage the crystal. A typical shutter assembly may consist of a waveguide gate and a solenoid that controls the position of the gate. When the radar system is not in operation the solenoid is not energized and the position of the gate is such that it causes a virtual short circuit across the waveguide path to the receiver input. When the radar system is in operation, the solenoid is energized and causes the gate to move from the waveguide to a position where it will offer no interference to signals traveling to the receiver.

TR AND ATR TUBES.—A simplified cross section view of a waveguide system duplexer is shown in figure 15-6. These tubes are a spark gap enclosed in a gas filled envelope. They are practical for this function because of the tremendous power difference between the transmitted and received signal. Ionization occurs during the transmitter pulse period and causes the tube to function as a short circuit or closed switch. During the reception period these tubes remain de-ionized because the received signals are low power; thus they appear as an open circuit.

The TR tube is used to protect the crystal mixer and the receiver circuits during transmission. When the magnetron fires, sufficient voltage is impressed on the TR tube to ionize it completely and break down the gap, producing an effective short circuit. Since the TR tube is placed an even number of quarter wavelengths from the waveguide a short circuit existing within the tube reflects an effective short circuit at the entrance of the receiver T-junction. This prevents the RF pulse from reaching the crystal and the receiver, but permits it to flow freely to the antenna.

The operation of the duplexer during transmission is shown in (A). After the pulse has passed, the tube de-ionizes and again presents a high impedance at the entrance of the receiver T-junction. This allows any reflected signals to reach the crystal mixer. Duplexer action during signal reception is shown in (B).

Figure 15-6.—TR/ATR action in a waveguide.

The ATR tube is located an even number of quarter wavelengths from the waveguide; thus when the transmitter fires, which breaks down the gap of the ATR tube, an effective short circuit is reflected across the opening at this T-junction. This causes the wall to appear continuous to the transmitter energy; thus the energy passes unimpeded.

The ATR waveguide section is so constructed than an even number of quarter wavelengths exists between its gap and the opening to the waveguide. During signal reception, the ATR tube is de-ionized and causes an affective open circuit to appear at the opening of the ATR junction. This causes a reflected short across the waveguide adjacent to the TR opening, as illustrated in (B). The received signal is guided into the TR cavity instead of continuing to the magnetron.

AC.173

Figure 12-5.—Separation of DME and non-DME equipped aircraft.

be protected on the overflown side, beginning at a point where the course change begins, is as follows:

a. FL 180 to FL 230 inclusive—28 miles.

b. Above 230 to FL 600 inclusive—34 miles.

AC.174

Figure 12-6.—Opposite direction altitude change.

4. After the course changes have been completed and the aircraft is back on course, the appropriate minima as specified in paragraph 1 applies.

5. For direct courses defined by degree/distance fixes (DME fixes of TACAN navaids which define a flightpath by a line connecting the fixes, not necessarily along a particular radial), the width of the protected airspace is 4 miles on each side of the route for flight below FL 180 and 10 miles each side of the route from FL 180 through FL 600.

INITIAL SEPARATION OF SUCCESSIVE DEPARTING AIRCRAFT

Initial separation between successive departing aircraft may be considered an interim measure to expedite departures. The controller must

10659

AC. 175

Figure 12-7.—Two illustrations of lateral separation.

plan ahead to insure that the initial separation applied will allow a smooth transition to at least minimum vertical, longitudinal, or lateral separation when the initial departure phase of the flight is complete.

Aircraft that will fly courses which diverge by 45 degrees or more after departing the same or adjacent airports may be separated by use of one of the following minimums:

1. Between aircraft departing from the same runway (fig. 12-11):

a. One minute until courses diverge when the aircraft will fly diverging courses immediately after takeoff.

b. Two minutes until courses diverge when the aircraft will fly the same course initially but will fly diverging courses within 5 minutes after takeoff.

c. Three miles until courses diverge when aircraft using DME will fly the same course initially but will fly diverging courses within 13 miles after takeoff.

2. Simultaneous takeoffs may be authorized when aircraft will fly diverging courses immediately after takeoff in the same direction from different runways whose centerlines are parallel and separated by at least 3,500 feet. (See fig. 12-12.)

3. Simultaneous takeoffs may be authorized from diverging, nonintersecting runways when aircraft will fly diverging courses immediately after takeoff and either of the following conditions exist:

a. The runways diverge by 30 degrees or more.

b. The distance between runway centerlines at and beyond the points where takeoffs begin is at least:

(1) 2,000 feet and the runways diverge by 15 fo 29 degrees inclusive.

(2) 3,500 feet and the runways diverge by less than 15 degrees. (See fig. 12-13.)

4. On intersecting runways, a succeeding aircraft may be authorized to take off when the preceding aircraft has passed the point of runway intersection and the following conditions are met:

a. The runways diverge by 30 degrees or more.

b. The runways diverge by 15 to 29 degrees inclusive and the preceding aircraft has commenced a turn. (See fig. 12-14.)

Aircraft that will fly the same course, when the following aircraft will climb through the altitude assigned to the leading aircraft, maybe separated by a minimum of 3 minutes until the following aircraft passes through the altitude of the leading aircraft. The minimum separation is 5 miles if both aircraft are using DME. (See fig. 12-15.)

Initial Separation of Departing and Arriving Aircraft

At airports where approach control service is provided, a departing aircraft may be separated from an arriving aircraft making an instrument approach to the same airport by using one of the following minima until vertical or lateral separation is achieved:

1. When takeoff direction differs by at least 45 degrees from the reciprocal of the final approach course, the departing aircraft must take off before the arriving aircraft leaves a fix inbound not less than 4 miles from the airport.

2. When the takeoff direction is not different by 45 degrees from the reciprocal of the final

approach course, the departing aircraft must take off so that it is established on a course diverging by at least 45 degrees from the reciprocal of the final approach course before the arriving aircraft leaves a fix inbound not less than 4 miles from the airport.

When the absence of an appropriate fix precludes the use of initial separation described in the preceding paragraph, and at airports where approach control service is not provided, a departing aircraft may be separated from an arriving aircraft making an instrument approach to the same airport by using one of the following minima until vertical or lateral separation is achieved:

1. When takeoff direction differs by at least 45 degrees from the reciprocal of the final approach course, the departing aircraft must take off 3 minutes before the arriving aircraft is estimated at the airport. (See fig. 12-16.)

2. When the takeoff direction does not differ by 45 degrees from the reciprocal of the final

approach course, the departing aircraft must take off so that is is established on a course diverging by at least 45 degrees from the reciprocal of the final approach course 5 minutes before the arriving aircraft is estimated at the airport or before the arriving aircraft starts its procedure turn. (See fig. 12-16.)

Visual Separation

Aircraft within control zones may be separated by one of the following methods:

1. The controller sees them and can provide visual separation.

2. The pilot sees the other aircraft and says he will maintain visual separation from it.

A nonapproach control tower may be authorized to provide visual separation between:

1. An arriving and a departing IFR aircraft.

EXAMPLE PHRASEOLOGY: RELEASE SUBJECT YOUR DISCRETION WHEN (Aircraft identification) IN SIGHT.

2. Arriving IFR aircraft within control zones when the weather is at or above basic VFR minima and the tower has reported that it has them in sight and visual separation can be applied.

AC.179

Figure 12-11.—Separation of departing aircraft using the same runway.

AC.180

Figure 12-12.—Simultaneous takeoffs from parallel runways.

10662

AC.181
Figure 12-13.—Simultaneous takeoffs from diverging runways.

Use of VFR and VFR Conditions on Top

An aircraft may be cleared to maintain VFR conditions when conducting flight under instrument flight rules if one of the following conditions exists:

1. A pilot requests such a clearance.
2. A clearance results in noise abatement benefits where part of the IFR departure route does not conform to an approved noise abatement route or altitude.
3. A pilot requests a practice instrument approach.

Aircraft may be cleared to maintain VFR conditions on top of a cloud, haze, smoke, or other meterological formation if the following conditions are met:

1. A pilot requests such a clearance.
2. The pilot is informed of the reported height of the top of the meteorological formation or that no report is available.

A VFR conditions-on-top type clearance may not be issued when pilot reports indicate weather conditions which are not suitable, or between sunset and sunrise, to separate holding aircraft from each other.

An alternative clearance must be issued to aircraft cleared to maintain VFR conditions when there is reason to believe that flight in VFR conditions may become impracticable, or to an aircraft cleared to maintain VFR conditions on top when the height of the tops is unreported.

A VFR-or VFR conditions on-top type clearance may not be issued to aircraft operating in positive controlled airspace.

Aircraft that operate VFR conditions on top must maintain a VFR cruising altitude/flight level. If a controller becomes aware that an aircraft on such a clearance is not an appropriate altitude for the direction of flight, the

AC.182
Figure 12-14.—Takeoffs from intersecting runways.

AC.183

Figure 12-15.—Takeoffs from the same runway when the succeeding aircraft climbs to the higher altitude.

pilot of the aircraft should be informed of the discrepancy.

No separation is provided for IFR flights operating in accordance with a VFR condition restriction.

Special VFR Operations

Only approved separation may be applied between special VFR aircraft and between such aircraft and IFR aircraft.

When vertical separation is applied to such operations, a fixed altitude is not assigned the special VFR traffic because of the clearance-from-clouds requirement. Special VFR aircraft would be cleared at or below an altitude which is at least 500 feet below any conflicting IFR traffic but not below the minimum safe altitude.

Helicopter Operations

The control of IFR helicopters is governed by the same rules and procedures as any IFR flight.

The control of special VFR helicopters is governed by the same special VFR procedures as any special VFR flight unless other procedures are covered in a Letter of Agreement.

At locations where the volume or complexity of helicopter operations warrants, a Letter of Agreement must specify the fact that special VFR helicopters are required to maintain visual reference to the surface and the traffic patterns, routes, and reporting or holding fixes necessary to achieve appropriate separation. This separation is based on specific criteria and is contained in chapter 4, section 9 of the TATC Handbook 7110.8 (Series).

RADAR IFR SEPARATION MINIMUMS AND PROCEDURES

This section contains primarily radar separation minimums. For a more detailed discussion of radar procedures, refer to chapter 13 of this training manual.

10664 10662

AC.184

Figure 12-16.—Separating departures from arrivals.

10665

Radar separation may be applied between the the following:

1. Radar identified aircraft.

2. An aircraft taking off and another identified IFR aircraft when the aircraft taking off will be identified within 1 mile of the end of the runway.

3. A radar identified aircraft and an IFR aircraft not radar identified when the indentified aircraft is climbing or descending through the altitude of the nonidentified aircraft and the following conditions exist:

a. The performance of the primary radar system is adequate.

b. The airspace in which separation is applied is not less than 6 miles from the edge of the radarscope (10 miles if 40 miles or more from the antenna site).

c. Flight data on the unidentified IFR aircraft indicates it is a type which can be expected to give an adequate primary return in the area where separation is applied.

d. The identified aircraft is vectored on a flightpath different from the route of the unidentified IFR aircraft before descent or climb.

e. Radar separation in maintained from all observed primary and radar beacon targets until nonradar separation is established from the unidentified aircraft.

Application of Radar Separation

Minimum radar separation is applied as follows:

1. Between the centers of primary radar targets. The primary target must not be allowed to touch another primary target or a beacon control slash (radar beacon or SIF target).

2. Between the ends of beacon control slashes.

3. Between the end of a beacon control slash and the center of a primary target.

Radar beacon targets may be used for separation purposes only if beacon range accuracy is verified by one of the following methods:

1. Correlation of beacon and primary targets of the same aircraft to assure that they coincide.

2. When beacon and primary targets of the same aircraft do not coincide, correlate to assure that any beacon displacement agrees with the specified distance and direction for that particular radar system.

If the beacon range accuracy cannot be verified, beacon targets may be used for traffic information only.

Separation Minimums

Minimum radar separation between airborne aircraft radar targets is 3 miles if less than 40 miles from the antenna site, and 5 miles if 40 miles or more from the antenna site.

Vertical separation applied between aircraft may be discontinued when the targets are observed to pass each other and no longer touch each other and their courses diverge by at least 15 degrees.

For single runway operations, a departing aircraft is spearated from an arriving aircraft on final approach by a minimum of 2 miles if separation will increase to a minimum of 3 miles (5 miles if 40 miles or more from the antenna site) within 1 minute after takeoff.

Simultaneous operations may be authorized on parallel runways, provided that the following conditions exist:

1. If the landing thresholds are even, the runway centerlines are separated by at least 3,500 feet. (See fig. 12-17.)

2. If the landing thresholds are staggered and one of the following conditions is met:

a. The approach is made to the runway nearest the arriving aircraft, the runway centerlines are laterally separated by at least 1,000 feet, and the thresholds are horizontally staggered at least 500 feet for each 100 feet of centerline separation below 3,500 feet. (See fig. 12-18.)

b. If the approach is made to the runway farthest from the arriving aircraft, the runway centerline separation exceeds 3,500 feet by at least 100 feet for each 500 feet of threshold stagger distance. (See fig. 12-18.)

3. The departure course will diverge immediately after takeoff from the missed approach course by at least 45 degrees until minimum radar separation is achieved and can be maintained.

4. Departing aircraft that have not commenced takeoff are held, or appropriate clearances issued to those committed to take off, when an arriving aircraft is observed to deviate from the approach/missed apporach course sufficiently to cause a potential conflict.

Simultaneous operations may be authorized on nonintersecting, diverging runways (fig. 12-19) provided that the following conditions exist:

1. The departure course upon or immediately after takeoff diverges from the missed approach course by at least 45 degrees until

10666

AC.185

Figure 12-17.—Simultaneous operations from parallel, even threshold runways.

minimum radar separation is achieved and can be maintained.

2. The distance between the centerline or extended centerline of the landing runway and the centerline of the takeoff runway (measured from the point where the takeoff is commenced) is as follows:

a. 1,000 feet if the runways diverge by at least 30 degrees.

b. 2,000 feet if the runways diverge by 15 to 29 degrees inclusive.

c. 3,500 feet if the runways diverge by 14 degrees or less.

3. Departing aircraft that have not commenced takeoff are held, or appropriate clearances issued to those committed to takeoff, when an arriving aircraft is observed to deviate from the approach/missed approach course sufficiently to cause a potential conflict.

Radar controlled aircraft are separated from the boundary of adjacent airspace, in which radar separation is also being used, by 1.5 miles when less than 40 miles from the antenna site, and 2.5 miles when 40 or more miles from the antenna site.

Radar controlled aircraft are separated from the boundary of airspace in which nonradar separation is being used by a minimum of 3 miles (5 miles when 40 or more miles from the antenna site). However, this separation is not required if the radar controlled aircraft are either climbing or descending and they are definitely outside of the airspace in which nonradar separation is being used.

A radar controlled aircraft that is climbing or descending through the altitude of an aircraft that has been tracked to the edge of the scope is separated by a minimum of 3 miles (5 miles when 40 or more miles from the antenna site) from the edge of the scope until nonradar separation has been established.

Radar controlled aircraft may be separated from prominent obstructions shown on the radarscope (displayed on the video map, scribed on the map overlay, or displayed as a permanent echo) by a minimum of 3 miles within 40 miles of the antenna site.

Vertical separation of aircraft above a prominent obstruction, which is displayed as a permanent echo, may be discontinued after the controller observes that the aircraft target has passed the obstruction.

10667

Notice that both tubes in this illustration are in the narrow section of the waveguide; thus they are E-type junctions, but they could just as easily have been in the wide dimension, making them H-type junctions.

Characteristics of TR and ATR Tubes. —At sea level pressure approximately 30,000 volts are required to break down a spark gap of 1 inch. Approximately 50 volts is required to maintain ionization; this is known as running voltage. Once the voltage has been removed, a lapse of approximately 10 μsec is required for de-ionization. By enclosing the spark gap in a partially evacuated envelope, the breakdown voltage will be reduced as well as the running voltage and the de-ionization time.

For efficient transmitter operation it is important that the power dissipated by the TR tubes is small as compared to transmitter power. Also the TR tubes must maintain a properly matched line while they are fired. During the time that the transmitter is fired the TR tubes must afford sufficient attenuation to prevent the power that leaks into the receiver from being of so great an amplitude that it may damage the receiver crystal. To allow scope presentation of nearby targets it is necessary that the TR tubes de-ionize rapidly.

The amplitude and duration of the ignition spike must be reduced to the extent that the receiver crystal will not be damaged. This is accomplished by providing a keep-alive voltage to the TR tubes. TR tubes that perform this function contain three electrodes, two of which provide the main gap which does the switching; the third is called the keep alive electrode. This keep-alive electrode is mounted close to one of the other electrodes. It is connected to a relatively high direct negative potential which causes steady partial ionization of the gas between it and the main electrode. This insures almost instantaneous firing of the TR tube for each pulse of the magnetron.

Recovery time may be described as the time required for a TR tube to de-ionize effectively. The length of the recovery time period is determined by the length of time required for the free electrons and ions, that remain in the gas after the transmitter pulse has been removed, to recombine. A short recovery time means that target echoes can be received sooner after the transmitter pulse ends.

The life of a TR tube is relatively short as compared with most other tubes. A major factor that shortens the life of these tubes is the gradual loss of gas pressure. This is the result of chemical combination of the gas and the tube electrodes; also molecules of gas become embedded in the electrodes as a result of glow and keep-alive discharge.

One means of lengthening the life of these tubes is to maintain the keep-alive current within design limits. Some equipments provide test points for making current checks. A reading lower than the normal minimum current will most likely be an indication that the TR tube is not operating at proper efficiency.

The most general indications of defective TR tubes are as follows:

1. Receiver recovery time will increase.
2. Receiver sensitivity will decrease.
3. Receiver crystals will become defective. (This will be indicated by an increase in crystal back current.)

Some radars use the same type tube for TR and ATR operation. In some cases a tube that will not operate as a TR may be used satisfactorily as an ATR; thus for emergency operation the tubes may be interchanged.

HYBRID DUPLEXER. —A type of duplexer somewhat different from those already discussed is the HYBRID RING. This duplexer is capable of performing the duties of the conventional ones already discussed, and in addition it has a low standing wave ratio and the ability to transfer high power.

The hybrid ring is a form of hybrid junction, which is a device that transmits power to two lines from each of two independent inputs that are not coupled together. This type of junction is frequently referred to as a "magic-T."

NOTE: This statement holds true for the hybrid ring duplexer only during reception; thus the magnetron is not coupled to the antenna and there is no dissipation of received power by the magnetron. The magic-T is discussed in greater detail later in this chapter and in chapter 12 of Basic Electronics.

During the transmitter pulse the duplexer does not function as a true hybrid ring because the ionization of the TR tubes by the high power transmitter pulse serves to couple the magnetron to the antenna. The TR tubes also perform their normal protective action for the receiver crystal.

RADAR RECEIVERS

Earlier in this chapter the importance of developing an extremely high powered pulse

When using a radar display with a previously specified beacon target displacement for radar separation purposes, 1 mile must be added to any minimum for a displacement of 1 mile or less between the primary target and the beacon target, and 2 miles must be added to any minimum for any displacement of more than 1 mile but not more than 2 miles.

AC.187

Figure 12-19.—Simultaneous operations from diverging, nonintersecting runways.

CHAPTER 13

RADAR AND ALLIED EQUIPMENT AND PROCEDURES

The name RADAR is formed from the initial letters of the words RAdio Detection And Ranging. Radar was developed principally for the purpose of detecting and ranging targets in wartime. This, of course, is still the primary purpose of military radar; however, the ability of radar to spot unseen objects has proven to be of great assistance in the problem of air traffic control. Civil and military aviation have grown to be a veritable giant compared to the days prior to World War II. The many departures and arrivals at major air terminals could not be effectively and safely controlled without the assistance of radar. Previous separation standards can be reduced, and this contributes to the expeditious and orderly flow of air traffic without any compromise of safety. In fact, safety is increased in many situations. Radar is used in many ways but, in this chapter, our main concern will be radar as applied in air traffic control.

HOW RADAR WORKS

ECHO PRINCIPLE

Radar depends on a principle that energy emitted from one point and traveling at a uniform rate will be reflected by obstructing surfaces in its path, in which case a small portion of the original energy returns, at the same rate of speed, to the point of origin.

This is the old principle of the echo, which we have all had demonstrated to us by sound waves. For example, the man who shouts at the side of a cliff to hear his echo is, in effect, illustrating the basic principles of radar, using sound waves instead of radio waves. (See fig. 13-1.) Radio waves that travel at the speed of light (162,000 nautical miles per second) also have echoes.

The nautical mile is used in this chapter because it is standard for navigation purposes, radar work, and when calibrating facilities.

FUNDAMENTALS OF RADAR OPERATION

In radar, the shout of our sound analogy is a short pulse from an ultrahigh frequency transmitter which generates electromagnetic waves that travel in very straight lines. (See fig. 13-1.) Upon striking an object, these waves are reflected and some of the energy returns to the transmitter sight where they are amplified by a receiver, and the elapsed time is measured very accurately. The Greek word "micro" means one-millionth of a unit; thus, one-millionth-second time unit is known as a microsecond. Despite the fact that radio pulses travel incredibly fast, electronic devices can accurately time these echoes.

Again, consider the man who shouts at the cliff. If he had cupped his hands around his mouth when shouting and around his ears when listening, he would have noted two improvements: First, the effective range of the echo would have been increased since the radiated sound waves were concentrated into a narrow beam and returning echoes were funneled into the ear; and second, he would have been able to more readily distinguish between two reflecting surfaces that were separated in azimuth from his position. This is of particular importance in radar if a high degree of accuracy of angular position is desired. The radar beam may be only one-half degree wide. Such a narrow beam can distinguish between two objects at the same range, differing by as little as 1 degree in angular position.

The radar antenna has two important tasks. It is not only required to radiate the radar pulse, but also has to catch the returning echo. The antenna array, or its size and shape, will vary

10670

AC.188

Figure 13-1.—Reflection of sound and radio waves.

with the performance requirements of the unit. Frequently some type of special directivity in the vertical or horizontal plane is required. In *the airport surveillance system, for example,* an ideal coverage would be from the ground to an elevation of 10,000 feet and ranges from 30 to 60 miles. Special antenna arrays have been designed to provide this coverage. The surveillance system of a ground controlled approach (GCA) unit is a prime example.

BASIC RADAR COMPONENTS

The basic components of a radar system are shown in figure 13-2. The function of each component is explained in the following paragraphs by tracing the sequence of events that go into the manufacture of a single blip on the indicator. (Part numbers used in this section refer to the number designation used in figure 13-2.)

Transmitting System

The transmitter power supply (1, fig. 13-2) provides a steady, high d-c voltage to the modulator.

The synchronizer (2) furnishes a sharp, low power pulse to trigger the modulator and the sweep generator simultaneously. These pulses are repeated between 60 and 4,000 times per second, depending on the design of the set.

The modulator (3) acts as an electronic switch or valve to furnish high voltage d.c. to the transmitter in brief pulses. These pulses *are extremely short (duration less than 1 micro-*second) in some equipment. After each pulse the transmitter is off the air while the system waits for echoes from that pulse to be received.

The maximum rapidity with which this cycle can be repeated has a direct bearing on the minimum distance over which targets may be detected. To illustrate, let us suppose you are bouncing a rubber ball against a wall. You are throwing the ball (transmitting the energy) with your right hand and catching the ball (receiving the reflected energy) with your left hand. As you get closer to the wall, you reach a point where you are physically unable to catch the ball and throw it again immediately. Something very similar happens in the radar set when the receiver, which has been disabled during pulse transmission, has not had sufficient time to return to operation when the return signal from a close-in target is received.

The transmitter (4) converts the d-c pulses received from the modulator into extremely high frequency radio energy. Frequencies used in aviation radar are:

BAND	FREQUENCY	USE
S	1,550 - 5,200 MHz	Airport Surveillance.
X	5,200 - 10,900 MHz	GCA Precision.
L	390 - 1,550 MHz	Long Range Surveillance.

AC.189

Figure 13-2.—Basic components of radar system.

Transmitter peak power of over 1,000,000 watts (1 megawatt) is possible with present long range radar. An appreciation of the large amount of power required for radar is evident if we compare this transmitter with commercial broadcast transmitters where 50 kilowatts is considered high power.

One factor which helps to make possible such high transmitter power in radar is that the transmitted signal is a surge of energy which lasts only for the very short interval that the pulse is being sent out. The high power components then have a period of rest during the time the receiver is in operation.

The waveguide (5) pipes the radiofrequency (RF) energy from the transmitter to the transmit-receive (T-R) box. "Pipes" is a descriptive term, inasmuch as waveguides are simply metal plumbing of rectangular cross section.

The T-R box (6) blocks the high power pulse of the transmitter from the receiver circuits. This is necessary to prevent the receiver system

10672

from being burned out by the extremely high-powered energy.

The waveguide (7) conducts the RF energy from the T-R box to the antenna.

The antenna (8) radiates the RF energy from the waveguide into the reflector.

The reflector (9) concentrates and shapes the RF energy into the desired beam.

Receiving System

The reflector (9), as well as directing the transmitted RF energy, catches the returning echo and concentrates this energy on the antenna.

The antenna (8) receives the echo energy from the reflector and transmits it to the waveguide (7).

Waveguide (7) pipes the echo energy to the T-R box.

T-R box (6) blocks off the transmitter circuits to allow all echo energy to be conducted into the receiver system.

The waveguide (10) pipes the echo energy into the converter.

The converter (11) mixes the RF echo pulses with a steady signal of a slightly different frequency, and transmits this combination to the receiver.

The receiver (12) converts the RF echo pulses to sharp video pulses. Video (from the Latin meaning "to see") output is analogous to the audio output of a conventional broadcast receiver.

The video amplifier (13) amplifies the video signals and feeds them into the control grid of the indicator.

The indicator power supply (14) furnishes relatively low voltages to the heaters, cathodes, and anodes of the sweep generator and the indicator.

The indicator (15) converts the video pulses received from the video into light indications and presents this information in the desired form. Practically all indicators are based on the use of a cathode-ray tube (CRT). The CRT, or "scope," is a conical glass bulb with an electron gun at the small end and a flattened glass disk at the other end. Their basic construction is somewhat similar to a television picture tube. (See fig. 13-3.)

The sweep generator (16, fig. 13-2) generates the variable current, which is applied to the deflecting coils, to sweep the electron beam back and forth inside the scope.

AC.190

Figure 13-3.—Cross section of cathode-ray tube with radar presentation.

RADAR DISPLAYS

There are numerous ways of displaying the radar data once it has been obtained. The manner of presentation depends upon the use to be made of the data. The most frequently employed type of presentation in air traffic control is a Plan Position Indicator, commonly referred to as the PPI-scope. In this type of display the time reference is at the center of the cathode ray tube face. Rangemarks are introduced into the system and show up as bright concentric circles on the display. Their spacing in terms of miles may be various values (1, 5, etc.), although at any one time the spacing will be uniform throughout the display.

The PPI-scope may be expanded for short ranges; for example, a 5-mile range may actually cover the same area on the face of the tube as a 30-mile range. The rangemark spacing interval may be manually changed or the indicator equipment may be of the type that produces a certain rangemark spacing interval for a specific range selected.

The offcenter PPI display is one in which the start of the sweep is moved away from the center of the tube face. One advantage of this type display is the increase in maximum range presented on the tube in a selected azimuth sector.

If 30 miles were the greatest range on a range selector switch, it would be possible to extend the sweep out to 60 miles in any desired sector by offcentering to the edge of the tube face. Whether targets could be seen out to 60 miles depends on the radar system itself and the type of target. Figure 13-4 shows two PPI-scopes with the same range selected but with one off-centered to increase range.

Targets show up on the PPI-scope as bright spots at their respective range and bearing from the antenna site. An example of a PPI-scope presentation is shown in figure 13-5.

This type display is commonly used for airport surveillance equipment which in conjunction with an aircraft's altimeter gives positive control of aircraft within the coverage of the radar equipment.

AC.191

Figure 13-4.—Advantage of offcenter PPI-scope.

AUXILIARY RADAR EQUIPMENT

A basic PPI display shows all types of radar echoes, both fixed and moving targets. Ground targets are usually displayed as strong echoes, and they will mask echoes from aircraft flying over these areas. Any echo that is undesirable, or that prevents the controller from observing aircraft, is called clutter. The moving target indicator eliminates clutter resulting from fixed targets.

Moving Target Indicator

The principle of the moving target indicator (MTI) is that the phase of the echoes from one transmitted pulse is compared with the phase of the echoes from the next successive transmitted pulse. If the phases of the two returns from the same target are the same, the returns cancel each other. If there is a phase difference, resulting from the target moving, the returns do not cancel, and there is an indication on the scope of moving targets only. The ability of MTI to display any specific aircraft target depends on the radial velocity of the aircraft. Radial

AC.192

Figure 13-5.—PPI-scope display.

16674

velocity is the speed an aircraft is making toward or away from the radar antenna, regardless of the heading or groundspeed. An aircraft target would not be displayed if it were flying a perfect circle around the antenna at a constant range; i.e., it would have no radial velocity.

The radar operator can control the video output from both normal radar and MTI. Normally, any of the following PPI displays can be selected by the operator (in some cases, the MTI range gate, or range of the MTI, is adjusted by a technician):

1. A completely normal radar display; signals from stationary and moving targets.
2. MTI display; uncanceled signals from moving targets only.
3. A display in which MTI signals are range gated at any desired range with normal signals appearing beyond the MTI presentation.

Figure 13-6 is an example of a 20-mile PPI display with the MTI range adjusted to 10 miles and normal radar appearing beyond that. The lines on the scope in figure 13-6 comprise a mapping system discussed later in this chapter.

Circular Polarization

A factor that determines the effective range of radar is the manner in which the radar energy is radiated into space. The radiation of electromagnetic (radar) energy during normal weather conditions gives good target returns. However, during a heavy rainstorm, the individual raindrops act as targets and reflect the polarized electromagnetic energy which may completely illuminate or clutter the scope and obscure any target that may be in the area. This condition is

AC.193

Figure 13-6.—A 20-mile PPI display with MTI adjusted to 10 miles.

AC.194

Figure 13-7.—Comparison of linear and circular polarization with MTI employed.

id675

undesirable and is overcome by radiating energy in a type of polarization that is designed to cancel returns from symmetrical targets, such as raindrops, while accepting returns from asymmetrical targets such as aircraft. This type of polarization is known as circular polarization.

Operator control of polarization is normally a two-position toggle switch labeled LP-CP (linear-circular polarization). LP is selected for normal operation and CP is selected when necessary to reduce clutter from precipitation. Figure 13-7 shows a comparison of linear and circular polarization used in conjunction with MTI. MTI will eliminate some precipitation clutter but normally precipitation is moving fast enough to be displayed as a moving target.

Caution should be exercised when using circular polarization in the control of certain types of aircraft such as the T-33 which normally displays only a very weak return. The CP will also reduce the target strength of aircraft targets and in some cases may eliminate it altogether.

Mapping Systems

A radar controller uses the rangemarks on the PPI and the compass rose around the edge of the scope to obtain the position of an aircraft target. Information from these two sources only gives range and azimuth from the radar antenna, and does not depict the geographical location of the aircraft; therefore some type of map display would be advantageous. Two types of mapping are available as integral parts of a PPI: a map overlay and video mapping.

The simplest solution is the map overlay. As the name implies, it is installed so that it covers the face of the cathode ray tube. The overlay is made of transparent plastic, and necessary reference marks, location of navaids, runways, and obstructions are etched into the surface. The overlay is edge-lighted, and the controller can control the brilliance. The shape of the overlay conforms to the surface of the CRT, but does not touch it.

There are two inherent disadvantages to the map overlay. Since the map is installed a short distance away from the tube, the targets do not appear in proper relation to the map unless the controller looks at the target from a point directly above the target. This is called parallax. Targets will apparently drift away from one of the etched courses, when the controller's viewing position changes. The controller must be extremely careful of his posture, so that he will observe the target correctly, and prevent parallax. The other disadvantage is that the map is only good for one range setting of the radarscope, since it does not expand with the display on the tube.

The video map is a great improvement over the map overlay. It is produced by a separate mapping unit rather than being installed on the radar console. A scale map of the desired features is drawn and then reproduced as a round photographic negative. This information is fed to the video amplifier ahead of the indicator tube and mixed with radar information from the receiver so that the resulting signals to the PPI will contain a combination of radar and map data. The antenna scan and the map scan are synchronized so the map is developed directly on the PPI as the sweep progresses. The result, and biggest advantage of the video map, is that the map expands or contracts as the range of the indicator is changed. The map coverage is in direct proportion to the area covered, and is accurate when the scope is offcentered.

Since the map is produced on the face of the tube along with the radar information, there is no parallax error. Thus, with a single map and mapping unit, a number of ranges with corresponding plotting information are available for display on several indicators operating independently of each other. Figure 13-8 is an example of a video map.

The video map is subject to some drift, but slight errors resulting from drift can usually be corrected by a radar technician. Another disadvantage of the video map is the possibility of failure of the mapping unit which would result in no map on the PPI.

SURVEILLANCE APPLICATION

Surveillance radar is a potent tool for all air traffic control use. It releases the controller from the restriction imposed by the uncertainty which formerly existed as to the actual position of the aircraft. Accuracies of the radar indications are superior to human vision, and a clear plan position of all aircraft and their approximate headings within the range of the radar is indicated. The many advantages of such a display are obvious.

It is evident that if a controller can continually see the position of an aircraft whose pilot is

AC.195

Figure 13-8.—Video map.

unable to see his position, he can relay information which will enable the pilot to make the necessary corrections in heading to bring him to his destination.

In the case of terminal radar operations, lines are drawn to show runway extensions, and usually are marked to indicate distances from the runway. Using any suitable radiotelephone, a controller can then give the pilot heading instructions which will keep his radar target accurately on the approach lines, and inform the pilot of the exact distance from the runway at any time. Knowing the sea level altitude of the airport, and the fact that a normal rate of descent for the desired glide angle is 300 feet per mile, a controller can advise a pilot what his altitude should be each mile. Such an approach is perfectly practicable under ceiling conditions of 300 feet or higher.

RADAR PERFORMANCE CHARACTERISTICS

MTI Blind Speed

When a radar system is developed that will detect only flying aircraft, and nothing else, the radar controller will have a nearly perfect system for controlling traffic. Such a system has not been developed yet but with the MTI system he has the next best thing. Nevertheless, radar systems do have limitations, and some of these are discussed in the following paragraphs.

If we review the principle of the MTI system, we find that the basic function of the MTI is to compare the phase of each signal received with that of the last signal return. The phase of each reply from a stationary target will be the same and the system will cause the returned signal to be canceled. If, however, the target is moving with a radial component of velocity with respect to the antenna, the reflected wave will have a different time phase from pulse to pulse and will be indicated on the radarscope.

Should an aircraft be moving at a speed such that the distance covered between pulses is equal to half the wavelength, or multiple thereof, of the transmitting frequency, the phase relationship is unchanged. As a result, the signal will be canceled in the same manner as the fixed target signal. Such a condition is known as MTI blind speed.

Blind speeds differ with each type and model of radar according to the wavelength of the transmitted signal. Complete loss of targets is seldom experienced with conventional aircraft since the propeller rotation will rarely be synchronized with the radial velocity of the radar and a partial return will be received. Seldom will an aircraft be able to maintain a course which affects MTI blind speed for more than a few seconds due to wind or variations in altitude.

Target Fades

An inherent feature of all radar systems with which the controller should become thoroughly familiar is target fading. Target fades will vary with the type of equipment, antenna height, tilt angle of the antenna, atmospheric conditions, and the surrounding terrain. Target fades will be apparent when an aircraft is over the antenna site. The degree and length of such a fade will be determined by the amount of antenna tilt. It should be noted that the lower the tilt angle of the antenna, the better will be the low angle coverage. On the other hand, the higher the tilt angle of the antenna, the better will be the high angle coverage. Most antennas are set to give maximum coverage for the particular type of control being employed.

The coverage in range, altitude, and azimuth for a particular site is determined by means of

10677

by the transmitter was discussed. Although the high power pulses are radiated in a narrow beam, only a small part of the radiated energy actually strikes a distant target. Since the energy striking the target is reflected or radiated over a wide angle, only a very small part of the transmitted energy is returned to the radar's antenna. Thus, the function of the radar receiver is to receive the weak target echoes from the antenna and amplify them sufficiently to provide the indicator with the desired target information. Consequently, the weaker the signal which the receiver can use, the greater the effective range of the radar set.

Before considering the detailed operation of the radar receiver, some of the requirements it must fulfill will be discussed. However, the discussion will be limited to those requirements that are within the scope of this course.

With the exception of some superregenerative IFF receivers, all modern radar receivers are of the superheterodyne type. The compnents of a typical receiver are a mixer, local oscillator, IF amplifiers, video detector, video amplifiers, and output provisions for built-in or remote indicators. The use of conventional RF amplifiers becomes progressively less practical from the lower radar frequencies to the higher and therefore are not used extensively in the microwave region. In cases where RF amplification can be used, the RF amplifier is placed ahead of the mixer. (Such application utilize traveling wave tubes.)

Improved receiver design has probably done more to improve the usefulness of radar than any other one thing. Radar receivers are quite sensitive, having been perfected to the point where they will accept signals in the order of a pico watt and will amplify and display them in many useful ways. The weaker the signal which a receiver can accept and efficiently display, the greater is the effective range of the set.

Signal-To-Noise Ratio

The name commonly given to small random fluctuating voltages present in the input stages of radar receivers is noise. In a radar set the noise voltages cause unwanted deflections of the electron beam in electrostatic deflection systems, and erratic fluctuations in intensity of the beam in intensity modulated systems.

Signal-to-noise ratio as well as proper bandwidth are important properties which are designed and built into receivers.

The noise level, at microwave frequencies, is practically all within the receiver. Most of the noise is generated in the amplifier stage and includes thermal agitation, shot effect, and induced voltages. Good design reduces these unwanted noises to a minimum but a strict maintenance schedule is necessary to maintain peak performance.

Bandpass

The input to the receiver amplifiers consists of minutes rectangular pulses of RF energy. In addition to being able to pass the carrier (intermediate frequency), the amplifying stages must be capable of amplify the modulation frequency. It should be recalled from Basic Electronics that a perfectly square wave consists of a fundamental frequency sine wave plus an infinite number of odd harmonics. Thus, to pass signals of this broad frequency range, radar receivers use amplifiers that have a relatively wide bandpass characteristic. Improper alinement of the receiver's amplifiers may cause distortion and loss of gain, resulting in poor target definition, reduction of range, and reduced accuracy of range measurements.

Radar receiver bandwidths may vary from 1 to 10 megacycles. The noises contained within the receiver include frequency components throughout the entire frequency spectrum and are, therefore, affected by the bandwidth of the receiver. Generally, a reduction in bandwidth reduces the noise voltage but does so at the expense of pulse shape. The amount of permissible distortion of the pulse shape thus limits the reduction in noise which may be accomplished by reducing the receiver bandwidth.

Tuning

Radar transmitters (magnetrons) used in aviation equipment have relatively poor frequency stability. As the radar antenna rotates, the antenna impedance may change. Thus, the load presented to the transmitter changes, and the output frequency of the magnetron changes. Other inherent factors cause considerable magnetron frequency shift over longer times. When the output frequency of the magnetron changes, the receiver must be retuned automatically if

1065

a flight check evaluation, which is conducted by the FAA flight check team before the facility is commissioned. In the event that a previously unknown fade area is suspected, another flight check should be requested in order to verify or confirm its existence. The data obtained from the flight check gives the controller an indication of coverage and target fades inherent in the type of equipment being used. In order to understand the capabilities and limitations of the system, a controller should become thoroughly familiar with the coverage pattern and fade areas which were determined by the flight check.

Anomalous Propagation

The atmosphere surrounding the earth is not uniform in density or moisture content; therefore, it is possible for local conditions to exist in which radar beams are bent upon passage through the atmosphere. Conditions under which the radar beam does not travel a straight line are called conditions of anomalous propagation. This condition is most apt to occur on days when there is little wind, and when air temperature is different from the ground temperature.

Anomalous propagation is most prevalent over water where water evaporation causes a temperature and moisture gradient to exist. The refraction of dry or dense air is greater than that of moist or less dense air; therefore radar beams will be bent in the direction of the dry or dense layers. Figure 13-9 depicts two conditions of anomalous propagation with the atmosphere causing a downward and upward bending of radar beams.

Under conditions depicted in figure 13-9, targets hundreds of miles away may be detected even though they are far below the horizon. On the other hand, relatively close targets may not be detected.

AC.196

Figure 13-9.—Anomalous propagation effect.

False Targets

The proficient radar controller must be quick to recognize temperature inversion as a false target. Such indications are often secondary reflections of radar energy from isolated refracting areas in a temperature inversion level. Correlation of radar reports with the Weather Bureau records indicates that a temperature inversion is usually present when unidentified flying objects appear on the scope. These inversions often travel across the radar at tremendous speeds and in changing directions. Apparently this phenomenon is produced by isolated refracting areas traveling with the wind at or near temperature inversion levels. Although the exact size, shape, and composition of these isolated areas are not known, it is believed that they may be atmospheric eddies produced by a shearing action of dissimilar air strata. It appears that such eddies may reflect and focus the radar energy with a lens effect to produce a small concentration of ground return with sufficient strength to show up on the radar display.

Radar Jamming

Jamming, as used in conjunction with radar, is defined as an introduction of false radiation into radar and radar devices. False targets produced by jamming may appear on the scope at varying ranges and bearings or in some cases may clutter large portions of the scope.

Jamming may be classified into two main categories, active and passive. Active jammers are those which generate radar energy producing interference. Passive jammers are those which act as parasitic radiators such as chaff. Chaff is thin strips of aluminum or other metal cut in a particular length. When released from aircraft at high altitudes, the strips float down to the ground slowly and the resultant echoes cause large areas of clutter.

The Air Force has equipped the ejection seats of some of their training aircraft with chaff dispensing bags. In the event of crew ejection, chaff will disperse over a wide area and will remain visible in the form of clutter on radarscopes for a period of 30 minutes or so depending on the altitude of ejection.

Controlled jamming is conducted by the military and regulated by the FAA to preclude interference with air traffic control radar. Controllers observing jamming operations, when no

10678

prior notification has been received, should notify appropriate authority. Figure 13-10 is an example of chaff interference.

Electronic Radar Interference

Interference from other radar installations operating on a similar frequency may be encountered when two or more radar installations are in close proximity. Such interference will appear as shown in figure 13-11. When this interference is encountered, nearby radar installations should be advised to check the frequency calibration of their equipment.

Also, most radar installations have dual channels so that a standby channel is always available. At times, the standby channel will transmit a signal that produces interference as shown in figure 13-12. In most cases, retuning by the technician will decrease the amount of interference.

AC.198

Figure 13-11.—Interference from another radar set.

SECONDARY SURVEILLANCE RADAR

Secondary surveillance radar is the international term for the air traffic control radar beacon system. This term refers to the form of secondary radar used only in air traffic control, and is not applicable to any other type of secondary radar. Secondary surveillance radar is a

AC.197

Figure 13-10.—Chaff interference.

AC.199

Figure 13-12.—Interference from the standby channel.

10679

separate system, and is capable of independent operation; however, in normal air traffic control use it is slaved with surveillance radar. A display of both the primary and secondary radar targets is presented on the associated plan position indicator. The term radar beacon is commonly used in reference to secondary surveillance radar. This term should not be confused with the term RACON which is a contraction for radar responder beacon. The RACON is a ground based navigational aid that emits a signal when activated by appropriate transmissions from an airborne unit. The operation of secondary surveillance radar is the reverse of a RACON.

The term radar beacon as used in this training manual will refer to a secondary surveillance radar system having as component parts a functioning interrogator on the ground, a functioning transponder in an aircraft, and a display on an air traffic control radarscope. When the word radar is used it will refer to a primary radar system. Primary radar differs from secondary surveillance radar in that it displays reflected signals rather than signals which have been transmitted by an airborne transponder.

Secondary surveillance radar effectively counteracts the following shortcomings of primary radar:

1. Aircraft reflection areas vary with size and configuration, thus limiting radar effectiveness.
2. The radar display may be degraded by weather conditions, especially precipitation.
3. Ground clutter frequently impairs the radar display, even though the radar is equipped with MTI.
4. Radar is more vulnerable to blind spots in the antenna coverage pattern.

Aircraft targets, unaided by airborne transponders, are not filtered but are displayed to controllers for all aircraft within the radarscope coverage. This includes those that are above, below, or beyond a particular area of control jurisdiction. Such targets clutter air traffic control displays and make the job of identifying one aircraft from another more difficult. Thus, the performance of essential air traffic control functions may be more complex and time consuming.

Development of Radar Beacons

A beacon system which was the prototype of those in use today was developed early in World War II, due to a need for some method of identifying an aircraft echo as friend or foe. This system used equipment on the ground to transmit an interrogation signal to the aircraft and a receiver/transmitter in the aircraft to transmit a response back to the ground station. The challenge, or interrogation, signal was received by the aircraft receiver and decoded. If the receiver/transmitter in the aircraft was set to respond to the challenge, the transmitter portion of the equipment sent a signal to the ground station. This signal was processed by the ground equipment and presented on a radar indicator. If the response was satisfactory, the aircraft was assumed to be friendly. As an IFF (identification friend or foe) system, the basic Mark X performed satisfactorily in its wartime role and made a valuable contribution to the progressive development of a secondary surveillance radar system.

Some basic Mark X transponders are still in use. However, they are programed to be discontinued, because without a coding capability, they are not compatible with the air traffic control environment. In this environment, radar beacon is used to identify and to provide radar services to individual aircraft rather than for identification of friend or foe.

The basic concepts of the modern radar beacon are essentially the same as those of the wartime IFF system. However, the capabilities of both ground and airborne equipment have been greatly increased. The result is an extremely versatile system which enables the radar controller to make rapid and positive identification of aircraft in nearly all conditions. In addition, it enables him to more effectively manage the display of data on his radarscope. This display management is accomplished through the use of the codes on mode 3/A which permit radar beacon targets to be systematically filtered. Through the use of target filtering, only those targets within a specific area and altitude (or altitudes) will be displayed to the controller concerned.

BASIC RADAR BEACON SYSTEM

The ground equipment of the system is made up of three major components—the I/R unit, the antenna, and the decoder. Included in the I/R unit are the interrogator (transmitter), the receiver, and the pulse pair generator. The major function of the interrogator is to generate distinctive radiofrequency transmissions in accordance

10680

with the mode in use. The action of the interrogator is similar to that of a primary radar transmitter as both transmit extremely short, powerful bursts, or pulses, of radio energy. In both systems the interval between transmissions is dependent upon the associated pulse repetition frequency (PRF); however, there is an essential difference in the transmission characteristics of the two systems. Radar transmits individual pulses while radar beacon interrogations consist of pulse pairs which are spaced in accordance with the interrogation mode. When a beacon system is used in conjunction with a primary radar, the interval between pulse pairs is related to the pulse repetition frequency of the primary radar equipment.

Simultaneous presentation of beacon and radar information requires that both system displays be correlated in range and azimuth. Range correlation is achieved by transmitting the beacon pulse pair a preset time before the radar pulse, in order to allow for the processing time in the transponder and in the decoder. A corresponding beacon pulse pair is not necessarily transmitted for every radar pulse. Azimuth correlation is accomplished by mounting both the beacon antenna and the primary radar antenna on a common pedestal. Consequently both antennas scan the same area simultaneously.

The receiver section of the I/R unit receives the replies from the transponder and passes them on to the decoder.

The decoder accepts beacon video and beacon trigger signals from the I/R unit. The beacon video signals are processed in the decoder, and then passed to the radar PPI. Beacon video may go either to the radar video mixer or directly to the console, depending upon the primary radar equipment being used. In either case the beacon targets are displayed on the PPI with the primary radar targets. The decoder performs several functions depending on the control setting.

The transponder is the airborne unit of the system. The basic parts of a transponder are a receiver, a signal processing unit, and a transmitter. A transponder is an active device; however, it may be partially quiescent. Before the transmitter portion will reply to an interrogation, specially keyed pulses must have been received and processed. When actuated, or triggered, the transmitter will emit a series of specific reply pulses which are independent of and stronger than echoed radar signals. (See fig. 13-13.)

AC.200

Figure 13-13.—Primary and secondary surveillance radar systems.

The response differs from an echo in several other respects:

1. The strength of the response is independent of the intensity of the interrogating signal received.
2. Interrogation and reply frequencies are not the same.
3. The response signal is different from the interrogation signal. (May be a coded or uncoded reply. This will be discussed later.)
4. A small delay is inherent between the receipt of an interrogation and the transmission of a reply. For standardization, this delay is adjusted to be 3 microseconds in duration.

FACTORS AFFECTING OPERATION

Both primary and secondary radars are subject to variances, both internal and external, that may adversely affect the operational efficiency of the equipment. A radar controller must know when to expect such things as fades, false targets, and interference. He must be able to cope with these situations when they occur on either the radar or the radar beacon equipment.

0R3d 10681

Secondary surveillance radar and primary radar both operate with signals received within the line of sight. A target must be within the line of sight. A target must be within the radiated antenna pattern and be within scope range in order to be displayed on a PPI.

Aircraft attitude will affect the quality of the display, since the transponder antenna is normally located on the underside of the aircraft. If the aircraft is in a turn, the wings or fuselage may block the pulse pairs transmitted by the interrogator, and the transponder may not be activated.

Buildings or other obstructing surfaces, usually within 2 miles of the beacon antenna site, will sometimes reflect either the interrogation or the reply. Reflections will cause a false target to be displayed at a different azimuth from that of the true target. These reflected targets are sometimes different in appearance from true targets and may be pivoted from the normal display position.

When two or more displayed aircraft with operating transponders are within 3.3 nautical miles of each other on the same general radial from the I/R, the reply signals may garble and the decoder equipment can cause the generation of false targets between the aircraft. Also, it may cause cancellation of parts, or all, of either or both actual returns. False targets or cancellations may occur even though altitude separation exists. Targets that are more than 3.3 miles apart will not be subject to decoder garble. Killer circuits in the decoder equipment will cancel garbled transponder replies.

A beacon target close to the antenna will sometimes be displayed as a concentric circle around the main bang rather than a distinct target on a definite azimuth. This display, called ring-around, is caused by maladjustment of the interrogator sensitivity. This maladjustment will permit the display of transponder replies received from interrogation by the side lobes or reflections of the antenna pattern.

Benefit may be obtained through use of the transponder low-sensitivity feature. With this, operation of a switch on the transponder control panel will reduce the sensitivity level of the receiver unit. Thus only the strongest interrogation signals will be accepted; generally the main lobes from I/R sites within 20 miles of the aircraft. Although most side lobes will be rejected, this feature should be used with discretion due to the greatly reduced effective range of the transponder.

Both primary and secondary radars display slant range. Slant range is the most direct line between the ground antenna and the aircraft. Thus the position of the aircraft, as displayed on a PPI, is only an approximate geographical position.

AIR TRAFFIC CONTROL RADAR BEACON SYSTEM

The standard secondary surveillance radar designed for use by FAA air traffic control facilities is the Air Traffic Control Radar Beacon System (ATCRBS) with 10 channel decoders. This equipment is not a modification or adaptation of existing or surplus systems. It has been designed specifically for use in air traffic control and is versatile enough to handle present needs of both the domestic and international beacon program, as well as anticipated future expansion.

Functions of the air traffic control radar beacon are:

1. Reinforcement of radar target.
2. Rapid target identification.
3. Extension of radar coverage area.
4. Transmission of altitude and other data.

If optimum performance is to be obtained, the requirements of U.S. National Standard for Common System Component Characteristics for the IFF Mark X (SIF)/Air Traffic Control Radar Beacon (Secondary Surveillance Radar) Systems, SIF/ATCRBS (SSR), must be met by all civil and military users of air traffic control radar systems under all expected operating conditions. The ATCRBS is in use at FAA facilities and the Mark X (SIF) is in use at military facilities as well as RAPCON's and RATCC's that are jointly operated by the military and the FAA.

The ATCRBS is capable of making interrogations in any four of the six different modes shown in figure 13-14. Mode A has been designated as the civil/military air traffic control mode. Since civil mode A is the same as mode 3 in military equipment, this common air traffic control mode is called mode 3/A. Modes 1 and 2 are military tactical modes; mode B has been designated a civil air traffic control mode but will not be used in the United States; mode C is to be used for automatic altitude transmissions. Mode D has been established but its use has not been specified.

A displayed transponder reply will appear as an arc of one or more concentric circles centered at the I/R site. The RAW VIDEO display appears as separate slashes (arc segments) for each of the framing pulses and information pulses. (See

10682

MODE	APPLICATION
1	MILITARY (IFF)
2	MILITARY (IFF)
3/A	COMMON (ATC)

C	CIVIL (ALTITUDE)
D	CIVIL (UNASSIGNED)

AC.201

Figure 13-14.—Interrogation modes.

fig. 13-15.) The series of pulses is called either a code train or pulse train. Identification pulses may be presented, and will be different depending on the transponder type. Complete code trains are displayed only if the decoder switch is set to

AC.202

Figure 13-15.—Examples of raw video displays, mode 3/A.

RAW VIDEO (CODE on UPA-24). This allows the reply signals to proceed directly from the I/R to the scope without decoding action.

In order to eliminate the clutter of numerous code trains, the radar controller can select discrete displays which are abbreviated and different from a raw video display. With the decoder set to display selected common system replies, the controller observes beacon targets as a maximum of two slashes. As a result it is easier to monitor beacon targets under conditions of heavy beacon traffic. Normally the slash of the beacon target display that is closest to the I/R site (main bang) is centered on the primary radar target.

MILITARY SECONDARY SURVEILLANCE RADAR

Standard Air Force secondary surveillance radar equipment is the Mark X selective identification feature (SIF). SIF equipment was designed for use by USAF facilities, but it is also used in RAPCON's which are jointly operated by the FAA and the Air Force. Secondary surveillance radar equipment used by the Navy is similar but different in capability as well as operation. The UPA-24 is the standard decoder at Navy facilities and jointly staffed RATCC's.

The abbreviation SIF is commonly used in referring to both the decoder and the transponder. SIF equipment is the basic Mark X IFF beacon that has been modified to make the transponder capable of transmitting coded replies, and the decoder capable of presenting displays of the decoded replies on a PPI. These decoders are capable of single channel selection only.

UPA-24 Decoder

Radar controllers at RATCC's are presently using radar beacon equipment with the decoder group UPA-24. This equipment, when interconnected with primary radar, provides interpretation of coded IFF signals. The UPA-24 accomplishes this by selecting a coded video pulse train in one of three modes. The coded pulse train is presented to the decoder circuitry and, if correctly coded, an indication in the form of a single decoded pulse is available for presentation on a radarscope. If the pulse train is not correctly coded, a decode pulse is not available for presentation.

The UPA-24 permits the presentation of the coded raw or decoded identification signal alone,

10683

the radar signal alone, or the radar signal mixed with either the coded raw or decoded identification signals. When used in conjunction with primary radar, the equipment provides decoding of IFF coded pulse trains in modes 1, 2, and 3. Thirty-two coded trains are available in mode 1; sixty-four coded trains are available in each of modes 2 and 3.

Most U.S. Navy radar beacon equipment, in its present form, is not compatible with the FAA ATCRBS in that it is not capable of providing all of the necessary features for the ATC common system. The equipment can only display one discrete code at a time—all other codes are not displayed. To display returns of all aircraft, it is necessary to utilize raw beacon video which clutters the radarscope and negates discrete decoding.

Figure 13-16 is a diagram of the Radar Set Control (Decoder) C-1008/UPA-24 operational controls and functions. Refer to figure 13-16 for a description of the operational controls and functions of the UPA-24 decoder in the following correspondingly numbered paragraphs.

1. Left-Hand Mode 1 Code-Selector Switch. This is a rotary switch having eight positions and is used to determine the desired first digit of a code pulse train for use in decoding mode 1 responses.

2. Right-Hand Mode 1 Code-Selector Switch. This is a rotary switch having four positions and is used in conjunction with the left-hand mode 1 code-selector switch, to determine the desired second digit of a pulse code for decoding mode 1 responses.

3. Left-Hand Mode 2 Code-Selector Switch. This is a rotary switch having eight positions and is used to determine the first digit of the desired codes for decoding mode 2 responses.

4. Right-Hand Mode 2 Code-Selector Switch. This is an eight-position rotary switch and is used in conjunction with left-hand mode 2 code selector switch, to determine the desired second digit of the codes for decoding mode 2 responses.

5. Left-Hand Mode 3 Code-Selector Switch. This is an eight-position rotary switch and is used to determine the desired first digit of the codes for decoding mode 3 responses.

6. Right-Hand Mode 3 Code-Selector Switch. This is an eight-position rotary switch and is used in conjunction with the left-hand mode 3 code-selector switch to determine the desired second digit of the codes for decoding mode 3 responses.

1. Left-hand mode 1 code-selector switch.
2. Right-hand mode 1 code-selector switch.
3. Left-hand mode 2 code-selector switch.
4. Right-hand mode 2 code-selector switch.
5. Left-hand mode 3 code-selector switch.
6. Right-hand mode 3 code-selector switch.
7. Mode selector switch.
8. IFF indicator.
9. GTC gate switch.

AC. 203

Figure 13-16.—UPA-24 decoder.

7. Mode Selector Switch. This switch is used to select one of three modes of coded pulse trains (modes 1, 2, and 3). It should be noted that this equipment is not designed for mode interlace.

8. IFF Indicator. Lighting of this lamp indicates that the radar recognition set is energized and power is on.

10684

9. GTC Gate Switch. This switch is used to control the duration of the gain time control (GTC), which aids in preventing saturation of the recognition set receiver by responses from nearby targets. It also selects the preset width of the receiver enabling gate. This gate enables the receiver to operate only during desired actual IFF operation, thereby reducing the overall noise contributed by the receiver. The switch is a toggle type for selection of either of two preset positions, LONG and SHORT.

10. IFF Gain Control. This potentiometer controls the gain of the IFF amplifier of the receiver portion of the recognition set. It revolves 270° clockwise for maximum gain.

11. VID Switch. This switch is used to select either coded or decoded video signals for presentation on the radar indicator. It is a toggle switch with two positions, CODE and DECODE.

12. Challenge Indicator. Lighting of this lamp indicates that the radar recognition set is challenging.

NOTE: The U.S. Navy definition of challenge is the transmission of the coded interrogator (IFF) signals.

13. Challenge Switch. This switch is used to select momentary or continuous interrogation of the recognition set. It is a three-position toggle switch with a momentary ON position; the other positions are LOCK-ON and OFF.

14. IFF-RDR-MIX Switch. This switch is used to select the IFF signals alone, radar signals alone or mixed radar and IFF signals. It is a toggle switch with three positions, IFF, RDR, and MIX.

Table 13-1 shows the various possible combinations of switch selection and the resulting display on a radarscope.

FUTURE USE OF ATCRBS

The general concept for the use of both identification and altitude codes is to provide the controller with a means of selectively limiting aircraft position, identify and altitude data displayed on his scope to that which pertains to aircraft under his control. It also provides an automatic display of the position and altitude of aircraft operating within a controller's airspace area of interest which are not operating on approved flight plans. Provisions will be made for the selective display of such data continuously, or at long or short intervals.

The DOD presently has a program of vast scope, designed to improve military IFF equipments. This program involves participation in the FAA plans for improving the ATC system during peacetime use of the national airspace. Identified by the acronym AIMS, derived from the title ATCRBS IFF Mark XII Identification Systems, the program calls for coordinated management by the Navy, Air Force, and Army.

Basically, the program will provide the following specific capabilities:

1. An increase to 4,096 from 64 codes on Mode 3/A.

2. Implementation of Mode C which will provide automatic altitude reporting in 500- or 100-foot increments.

3. An improved military IFF system.

Besides implementing the specific capabilities, the AIMS program has a significant objective of standardization so that overall operational requirements of FAA's national standards are met.

The equipment designed for the ground environment is the Direct Altitude and Identity Readout (DAIR) system. The basic function of the equipment is to provide digitally derived synthetic display markers for the readout of beacon-furnished target information.

The synthetic target markers will be of several types, depending upon the nature of the reply codes and selections made at the display control boxes. Numerical readout of identity reply codes and/or pressure-corrected altitude information will be presented in close-association with the target markers. Special markers and alarms for emergency and communication failure replies will be presented, and discrete markers will be generated for code-selected targets and for aircraft flying within a selected altitude zone.

In the generation and presentation of synthetic markers and numerical tags for beacon information, the system capability for display of primary radar information will be preserved. A backup presentation will also be provided wherein beacon decode signals are displayed, as is presently done with secondary surveillance radar.

Figure 13-17 is an example of the various displays that may be available with the DAIR equipment.

10685

Table 13-1.—Mark X (SIF) Transponder—UPA-24 decoder displays.

Code VID Decoder	IFF RDR-MIX-	Mode	Display
Code	IFF	3	One slash for each pulse in the code trains; two successive code trains for I/P (IDENT); four successive code trains for EMERGENCY. Only beacon targets will be displayed.
Code	RDR	3	Only primary radar targets will be dsiplayed.
Code	MIX	3	One slash for each pulse in the code train; two successive code trains for I/P; four successive code trains for EMERGENCY. Both beacon targets and primary radar targets will be dsiplayed.
Decode	IFF	3	One slash if transponder code has been selected on decoder. Only beacon targets will be displayed.
Decode	RDR	3	Only primary radar targets will be displayed.
Decode	MIX	3	One slash if transponder code has been selected on decoder. Both beacon targets and primary radar targets will be displayed.
ANY POSITION	ANY POSITION	2 or 1	Display will be same as for mode 3.

NOTE: Code 7700, I/P, and EMERGENCY will be characteristic display only when CODE-DECODE switch is in CODE (same as RAW VIDEO) position.

Figure 13-17.—DAIR display legend.

TYPES OF ATC RADAR EQUIPMENT

Ever since naval aircraft operations began, the Navy has actively sought to develop reliability in all-weather landing systems both ashore and afloat. Research and development of such systems is a continuous process taking advantage of new equipment and ideas as they are introduced. Now, because of precision radar, high speed data processing, and microcircuit electronics, new equipment is being introduced at a fairly fast pace.

In this section, an attempt is made to briefly describe radar equipment in general use, leaning toward newer equipment. It is not intended to be all-inclusive or a substitute for familiarity with the equipment in use at your facility; neither is it a substitute for study of the operator's section of the applicable technical manual.

GROUND CONTROLLED APPROACH EQUIPMENT

Ground controlled approach (GCA) is a radar system providing air navigation to an aircraft. Through the use of air surveillance radar, precision approach radar, and radio communications, a ground operator assists a pilot in his approach during weather conditions of low visibility and ceilings. No special airborne electronic components are required. Thus, a two-way functioning radio is all that is necessary in the aircraft.

The GCA unit consists of a surveillance radar system and a precision approach radar system (PAR) for controlling the initial and final approach portion of an approach. The surveillance radar is displayed on a PPI scope. The PAR is displayed on an AZ-EL scope providing the controller with a precision radar picture of azimuth and elevation coverage in the final approach area. (See fig. 13-18.)

Figure 13-19 shows the AN/CPN-4 GCA unit. This unit is a self-contained, mobile radar unit designed for controlling and landing of aircraft during periods of reduced ceiling and visibility.

GCA QUADRADAR AN/FPN-36

The FPN-36 is actually four radar sets in one. The operator sits before the single 12-inch scope and with a selector switch, displays the desired radar function—surveillance, precision, height finding, or airport taxi control.

Some of the advantages of this equipment are:

1. Small, light, and easily transportable.
2. Only one operator required.
3. Minimum cost.
4. All four systems on one scope.
5. Multiple runway coverage from one location.
6. Circular polarization.

The two main disadvantages of this equipment are: Only one aircraft can be worked at a time; and without two units, the search and precision system cannot be monitored simultaneously. No IFF/SIF capability is available.

10687

it is to receive the reflected echoes. Therefore, radar receivers must have the necessary circuitry to provide for automatic tuning—commonly called automatic frequency control (AFC).

Functional Operation

Radar receivers found in aviation equipment use syperheterodyne circuits of the single-conversion type (single-intermediate frequency). Superheterodyne receivers are discussed in detail in chapter 14 of Basic Electronics, and should be studied prior to continuing in this chapter. Although the receiver circuits discussed are primarily broadcast and communication receivers, their basic principles of operation are applicable to radar receivers.

Radar receivers differ from communication receivers in the following respects: (1) most radar receivers must detect received signals of approximately the same amplitude as the random noise generated by resistors, vacuum tubes, and other electronic components in its input stage; (2) radar receivers must be much more sensitive than communication receivers, in which static limits the smallest signal that can be heard; and (3) radar receivers must receive very short pulses of RF power reflected from distant targets. The pulses returned to a radar receiver have widely varying amplitudes and distorted waveshapes. To determine target range accurately, pulse wave fronts must rise very rapidly. To reproduce these rapidly changing signals, the radar receiver band-pass must be very wide.

The block diagram illustrated in figure 15-7 is representative of a typical superheterodyne type radar receiver which is found in most airborne radar sets.

Referring to the block diagram, it should be noted that RF energy from the antenna is fed to the mixer. Crystal mixers are used as the first stage in radar receivers because of their high signal-to-noise ratio. The actual construction and operation of crystal mixers was discussed in chapter 12 of this course.

The local oscillator, a special type high-frequency oscillator called a klystron, couples its output through the waveguide to the mixer. The theory of operation, its adjustments, and tuning procedure will also be discussed later in this chapter. The local-oscillator frequency beats with the transmitter frequency (heterodyne action) and produces the IF (intermediate frequency), which is the frequency resulting as the difference between the local-oscillator and the transmitter frequencies. This difference frequency may range from 30 to 100 mc, but in most receivers the IF is either 30 or 60 mc.

AC.205

Figure 13-18.—Functions of a GCA unit.

AN/FPS-8 RADAR

The AN/FPS-8 radar is a medium range surveillance radar used in most RATCC's. It has a range of approximately 200 miles for both primary and secondary (SIF) radars, and an altitude range of 40,000 to 50,000 feet.

AN/FPN-28 RADAR

This radar system is the short range search and precision approach radar remotely operated from the RATCC building. The search has a range of 30 to 50 miles and an SIF range of 200 miles where SIF equipment is installed. The

10688

AC.206

Figure 13-19.—AN/CPN-4 GCA unit.

10688

precision radar has a range of approximately 10 miles in the final approach area.

AN/FPN-47 RADAR

The AN/FPN-47 is the standard surveillance radar system in general use by the FAA, Air Force, and Navy in airport surveillance as part of the air traffic control system. This system is replacing or has replaced the FPS-8 radar and the search portion of the FPN-28 radar at Navy ATC facilities.

This system has a maximum radar video range of 60 miles and a maximum SIF/beacon range of 200 miles. The SIF/beacon video can be displayed in conjunction with the normal and MTI video on all sweep ranges except the 200-mile range. With the 200-mile range selected, radar and SIF/beacon video are displayed simultaneously for the first 60 miles of the sweep, and SIF/beacon video only is displayed from 60 to 200 miles. Six fixed ranges of 6, 10, 20, 40, 60, or 200 miles may be selected by the operator, and two variable sweep ranges are available for selection from 6 to 60 miles. The 6- and 10-mile ranges provide range marks at 2-mile intervals; the 20-, 40-mile, and first variable range at 5-mile intervals; the 60-mile and second variable range at 10-mile intervals; and the 200-mile range at 25-mile intervals. The altitude range of the FPN-47 is from 0 to 10,000 feet MSL.

An electronic cursor and range strobe is also provided with this equipment. The cursor origin may be selected as centered with the radar sweep or offcentered and manually positioned on any desired target and cursor azimuth alined and range strobe positioned on any other target. Then the target range and bearing can be read from indicators on the front panel of the PPI console. This provides accurate range and bearing of targets from the antenna site (centered) or relative range and bearing between two targets (off-centered).

The surveillance position illustrated later in this chapter, under the heading Radar Air Traffic Control Centers, shows the PPI console used in the FPN-47 radar system. For detailed information on the capabilities and operating controls used by operators, refer to the appropriate technical manual for this equipment.

AN/FPN-52 RADAR

The AN/FPN-52 is the standard precision radar system in general use by the FAA, Air Force, and Navy. This precision radar system is replacing or has replaced the precision portion of the FPN-28 radar at Navy ATC facilities.

The function of the FPN-52 is the same as that shown in figure 13-18 for the precision portion of a GCA unit. In order to track both the course and the glidepath of aircraft on approach, the antenna system of this radar scans or "looks" in both the vertical and horizontal planes. The two scans (elevation and azimuth) are shown on the map face of an AZ-EL scope as shown in figure 13-18.

The coverage of the FPN-52 is 7 degrees in elevation and 20 degrees in azimuth in the final approach area with a range of at least 8 miles. Normal and MTI video, range marks at 1-mile intervals, cursors (centerline and glidepath), and servo data information are displayed on the AZ-EL scope. A logarithmic time base sweep is used on the AZ-EL indicator to give greater emphasis to more critical, close-in targets. Thus the glidepath cursor appears slightly curved on the scope although it represents a straight line in space. The first few range marks are comparatively far apart and the more distant ones are comparatively close to each other. An aircraft will appear to pick up speed on its approach as its range decreases. An approaching aircraft may be tracked by means of the antenna servo. Antenna servocontrol is used to move the azimuth antenna up or down and/or the elevation antenna right or left. This allows the controller to center the radar beam on the aircraft even though it may be considerably off the desired course or glidepath.

The precision position illustrated later in this chapter shows the AZ-EL scope used with the FPN-52 radar system. For more details on the capabilities and operating controls used by operators, refer to the appropriate technical manual for this equipment.

ALL-WEATHER CARRIER LANDING SYSTEM (AWCLS)

The AWCLS is a combination of several systems developed independently, each of which performs a significant function in the complexity of automatic landings. The AWCLS consists of precision tracking radar coupled to a computer data link to provide continuous information to the aircraft, and independent beam scanning transmitters which provide the pilot with a monitoring capability and a backup approach system.

10690

AN/SPN-10 RADAR

The AN/SPN-10 was the first radar system developed to provide the carrier landing capability described in the preceding paragraph. Since its development, system reliability has continuously improved through testing and newly acquired technology. The latest improvement concerns the conversion of the AN/SPN-10 to a digital system using solid state radar. This converted system has been designated the AN/SPN-42.

AN/SPN-42 RADAR

In addition to precision tracking radar, the AN/SPN-42 consists of the necessary electronic equipment to provide a completely automatic landing capability. When an aircraft is approaching a carrier, the precision tracking radar monitors the aircraft's progress and feeds position information to a computer. There the aircraft's position is measured in relation to a preselected approach path. The computer determines what corrections are necessary to maneuver the aircraft to the desired path and transmits this information to the aircraft by radio. Equipment in the aircraft feeds the commands through an autopilot to the aircraft's control surfaces and throttle and the aircraft reacts accordingly. (See fig. 13-20.) This same information, in addition to intelligence concerning the distance from the ship to the aircraft, is also fed to the CCA operator's console. An example of the operator's console is shown in figure 13-21. The information may also be presented on an ILS type instrument display for the pilot as a visual presentation of error information and corrections to be made. Thus, three modes of operation are available for landing approaches—(1) fully automatic, (2) manual approach similar to a conventional ILS type approach, and (3) conventional CCA approach in which the aircraft is talked down by the controller.

AN/SPN-41 SYSTEM

The need for the pilot to monitor his progress during a fully automatic approach was recognized early in the development of AWCLS. To provide the pilot with this capability, the AN/SPN-41 was developed. This is a completely independent guidance system which, in addition to providing a means for monitoring, affords the pilot another method of making an instrument approach to the ship. In this system, shipboard transmitters scan coded microwave signals alined on the desired approach path. On the aircraft's instrument panel, the information from this system is displayed on an ILS type instrument. This is illustrated in figure 13-22. The AN/SPN-41 provides guidance information in excess of 20 miles. This type approach requires the pilot to transfer to a visual landing aid, such as the Fresnel lens system, prior to touchdown as would mode two or three approaches using the AN/SPN-42.

AC.207

Figure 13-20.—AWCLS method of operation.

10691

When both the AN/SPN-41 and AN/SPN-42 are installed in aircraft and ships, the SPN-41 will serve as a feeder and monitor system for the AWCLS. The SPN-41 furnishes the pilot with information on the same ILS type instrument as does the SPN-42 for a mode 2 operation. Since modes 1 and 2 may be lost or the data link system could possibly fail in the SPN-42 system, the SPN-41 provides backup for continuation of a mode 2 type approach should an equipment failure occur while an aircraft is on an approach.

Of course, the ever-present CCA controller monitors the entire system on the operator's console and is always there to transition to a mode 3 or conventional talkdown approach when necessary or desired.

RADAR AIR TRAFFIC CONTROL CENTERS (RATCC)

Established by the Navy at many major Fleet Support air stations and All-Weather air stations to meet the trend of increased aircraft performance and increased air traffic under all types of weather conditions is the Radar Air Traffic Control Center. A RATCC is designed to provide radar service at ranges beyond those of ordinary GCA equipment. With modern, permanently installed radar equipment, these facilities have an increased capacity for handling IFR traffic. As an Air Controlman, you may be ordered to duty at one of these centers, or to a station that coordinates with one.

AC.208

Figure 13-21.—AWCLS operators console.

10692

AC.209

Figure 13-22.—AN/SPN-41 approach system.

The mission of a RATCC is to provide safe, orderly, and expeditious movement of air traffic within a facility's area of control, to and from operating areas, and into and from the national airspace system.

The concept of RATCC is to provide the approach controller with the added capability of radar, thereby enabling him to control traffic more safely and expeditiously.

RATCC facilities are manned on a 24-hour basis. Consequently, there is seldom any delay involved in taking control of inbound or outbound traffic. A minimum of 800 approaches per month is considered necessary for a RATCC to maintain its operational proficiency. The normal complement of a RATCC is 7 officers and 69 enlisted men.

The RATCC central control room is located in the operations building and accessible to the visual control tower. This room contains remote indicating scopes and control consoles for each of the following radar equipments: Medium Range Air Traffic Control Radar; Short Range Air Traffic Control Radar; Precision Approach Radar; and certain other maintenance and operational controls. Additional equipments located in RATCC are large direct-view type situation display boards for the traffic control radars; VHF/UHF DF equipment; IFF/SIF equipment; a selective communications and intercommunications system; wind direction and velocity indicators; as well as an altimeter setting indicator. At stations that utilize the closed TV circuit for weather briefings, a TV set may also be installed.

Figure 13-23 is a diagram of a RATCC floor plan. Since the control problems, space available, and the equipment allocated for each location will vary, it is natural that each RATCC floor plan will vary as well.

Figure 13-24 shows an ASR and PAR operating position including the communications equipment. The communications equipment may be the AN/FSA-17 or AN/FSA-52 communications console which is discussed in chapter 4 of this rate training manual.

10693

AC.210

Figure 13-23.—RATCC floor plan.

INTERRELATIONSHIP OF OPERATING POSITIONS

In order that all phases of the air traffic control function at a RATCC facility be adequately manned by competent controllers at all times, general knowledge of the duties of all operating positions is a must. This policy is strongly recommended in current OpNav Instruction 3721.1 (Series). This cross training of personnel at a RATCC facility creates an extremely flexible air traffic control division. Also, when a controller transfers, he has undoubtedly gained valuable experience that should benefit not only himself but his next duty station as well. The instruction previously mentioned directs commanding officers to make suitable entries in the service record of a man considered properly qualified to control instrument traffic.

Certification and Qualification

Due to the nature of their importance to the Air Controlman, the qualifications and certificates necessary for the enlisted positions at a RATCC are printed verbatim from OpNav Instruction 3721.1 (Series) (enclosure (2)).

APPROACH CONTROLLER.—The Approach Controller will possess a Control Tower Operator's certificate with a senior rating for the appropriate area or an Air Traffic Control Specialist (ATCS) certificate with an area rating. His general duties, in addition to such supplementary duties as may be assigned by the RATCC watch officer, are as follows:

1. Control and coordinate the movement of all instrument traffic in accordance with existing regulations and directives.
2. Issue air traffic clearances and information to all aircraft which are operating under the jurisdiction of the RATCC.
3. Maintain radar surveillance of air traffic, monitor approaches, vector inbound and departing aircraft, and provide radar assistance to aircraft as required.
4. Determine the interval to be used between successive approaches, taking into

10694

AC.211

Figure 13-24.—ASR and PAR operating positions.

consideration all aspects of the air traffic control sideration all aspects of the air traffic control situation at the time, including the following: weather, runway in use, reliability of radar equipment, reliability and sufficiency of communications, types of aircraft under control, runway acceptance rate, and other factors which may affect operations.

5. Provide assistance and priority of services to aircraft in emergency situations.

6. Utilize any or all other operating positions as necessary to assist in the control of air traffic.

ASSISTANT APPROACH CONTROLLERS.—The Assistant Approach Controller will possess a Control Tower Operator's certificate with a senior rating for the appropriate area or an ATCS certificate with an area rating. In order to provide the maximum flexibility of operations, the RATCC officer is authorized to modify the duties of this position as the local situation dictates. His general duties may include the following:

1. Assist the Approach Controller in the control and coordination of the movement of all IFR traffic as directed.

3. Air Operations Supervisor.
4. Section Leader.
5. Radio Operator-Ship/Shore Communications.
6. Land/Launch Recordkeeper.
7. Status Board Keeper.
8. Teletype Operator.
9. Dead Reckoning Tracer (DRT) Operator.
10. Sound-Powered Telephone Talker.

The duties and responsibilities of Air Operations' personnel assigned the operating positions below the section leader level are discussed here.

Radio Operator

The radio operator establishes and maintains radio communications with shore activities on Raspberry, Air Defense Liaison, and intratype frequencies as applicable. He insures that the AIR OPS officer sees all messages received. He also is responsible for the following:

1. Maintains a routine message log and the message boards for the CATCC.
2. Makes sure that all messages are initialed and filed.

Land/Launch Recordkeeper

The person in this position mans the 2JG sound powered aircraft information circuit and uses it to relay information to pilots' readyrooms as a followup to the interior teletype. He also:

1. Maintains the ship's aircraft launch and landing log.
2. Insures the accuracy of aircraft calls, side numbers, and pilot's names on the status boards.

Status Board Keeper

The status board keeper uses a split headset to man both the 2JG circuit and the land/launch frequencies. He also records pertinent information relayed to him on the status board including the fuel state of each aircraft.

Teletype Operator

This operator is in charge of the teletype transmitter for the CATCC. Receiver repeaters are located in pilots' readyrooms to promulgate information to pilots, such as changes in flight schedule, weather, ship's intended movement, etc.

DRT Operator

The operator of the Dead Reckoning Tracer:

1. Knows the location of maps, charts, and publications used in CATCC.
2. Provides bearing and distances of nearest land and airfields to CCA, CIC, Pri-Fly, and status board keeper every half hour, and at other intervals as specified by the Air Operations Officer.
3. Properly operates the DRT and periodically checks the ship's indicated position with the ship's navigator.
4. Makes sure the navigation information on the status board is accurate.
5. Keeps up-to-date information on danger areas, operating areas, firing areas, etc., on the chart in use.
6. Obtains path of intended movement (PIM) information from navigation personnel and check its relation to flight advisory areas and other control areas.

CCA

The contraction CCA as used in this instance is expanded to include all those operating positions involved in the actual radar control of airborne aircraft under the Operations Officer's cognizance except those being controlled by the Combat Information Center (CIC).

In many instances some of these positions may be combined due to personnel shortages. However, an ideal arrangement is as follows:

1. One CCA Officer.
2. One Assistant CCA Officer.
3. One CCA Supervisor (normally a CPO).
4. One Departure Controller.
5. One Departure Status Board Keeper.
6. One Marshal Controller.
7. One Marshal Status Board Keeper.
8. Two Approach Controllers.
9. Two Final Controllers.
10. One CCA Approach Status Board Keeper.
11. Two Sound-Powered Telephone Talkers.

The duties and responsibilities of some personnel below the supervisor level assigned to CCA are discussed in the following paragraphs.

NOTE: For explanation of unfamiliar terms, refer to the list of definitions following this section.

10697

The IF amplifier consists of a preamplifier and an IF strip. The preamplifier is physically located near the crystal detector to prevent loss or attenuation of the signal before it can be amplified. The input circuit of the first preamplifier stage is tuned to the intermediate frequency, which is the difference between the transmitter and local oscillator frequencies, and bypasses all other unwanted frequencies to ground. (NOTE: It is in this section of the receiver where noise generation must be rigidly controlled.) The preamplifier normally consists of at least two stages of amplification, the first of which may be a cascade type. Its output is fed to the main amplifier which is normally referred to as the IF strip.

The IF strip consists of several stages of double-tuned IF amplifiers. They are double tuned to broaden the band pass of the receiver for better fidelity. The gain of the IF amplifier is normally between 10^6 and 10^{12}, and can be varied by altering either the control grid bias or the screen voltage of one or more stages.

The greatly amplified signal is then fed to the detector, usually a conventional diode detector, where the video signal is removed from the IF carrier. The detector filters used in most airborne radar receivers must be a long RC filter to the IF frequency and a short RC to the video envelope. Thus, the intermediate frequency is shorted to ground and the detected video pulses are passed to the next stage.

The video amplifier receives the detected pulses and amplifies them to the magnitude required to operate the indicator. The input to the video amplifier is in the form of rectangular pulses which are made up of infinite number of odd harmonics. Therefore, the video amplifiers must be designed for a wide band-pass in order to amplify the principal harmonics and preserve the shape of the input waveform.

The output from the video amplifier is fed to the video output cathode follower. The cathode follower is used as an impedance matching device between the video amplifiers and the indicator. It also serves as a power amplifier to drive the indicator. In the case of remotely located indicators, it is also used to match the impedance between the video amplifiers and the interconnecting coaxial cable.

The last block to be discussed in figure 15-7 is the AFC circuit. The AFC circuit is used to automatically adjust the local-oscillator frequency so that the radar receiver is always tuned to the radar transmitter frequency. Remember, the loading of a radar transmitter often changes as the transmitting antenna rotates (scans). The frequency of a microwave oscillator is very sensitive to changes in load impedance. Thus, as the transmitting antenna of a microwave radar is rotated, the transmitter frequency changes. If the local oscillator frequency does not also shift, these frequency changes may be so great that the received signal is outside of the receiver band-pass. In these cases AFC is used to automatically track the radar receiver tuning with the transmitter frequency.

Although many different types of automatic frequency control circuits are used in microwave radars, all AFC systems are basically similar in operation. Practically every AFC system has circuits that produce an output voltage proportional to the change in transmitter frequency. This output voltage changes the local-oscillator output frequency in such a way that the radar receiver remains tuned to the transmitter frequency.

INDICATORS

The purpose of the indicator and its associated components is to display target information supplied by the receiver and antenna system. The indicator may be a relatively simple device such as an indicating light that goes ON and OFF when specific conditions exist, a small meter, or an elaborate assembly containing a cathode-ray tube (CRT). However, in any case the complexity of the indicating system will vary with the amount of information to be displayed to the operator.

In most cases the technician will be working with the CRT type of indicator. This type indicator is the only one discussed in this chapter. CRT indicators may also vary in degree of complexity and may be used to display numerous data simultaneously to the operator. Some of the data presented to the operator are as follows:

1. Target range.
2. Range rate.
3. Target position.
4. Artificial horizon.
5. Steering references.
6. Altitude.

1067 8801

Departure Controller

Primary responsibility for adherence to the assigned departure rests with the pilot; however, advisory control is normally exercised, with a shift to close control as required by weather conditions, upon request, or when the assigned departure is not being adhered to. In addition, the departure controller is responsible for the following:

1. Insure that communications and positive track are established with all aircraft to the extent possible under existing electronic emission control (EMCON) conditions.
2. Request navaid checks as necessary.
3. Maintain advisory control of departing point-to-point flights until pilots shift to en route frequencies, and of other aircraft until control is accepted by CIC or another controlling agency.
4. Before releasing aircraft to another controlling agency, give each pilot (flight leader) any pertinent information such as changes in composition of flight, changes in PIM, or in mission.
5. When transferring control to CIC, give CIC the range and bearing of the aircraft being transferred, and insure that CIC acknowledges assumption of control.

Departure Status Board Keeper

The Departure Status Board Keeper maintains the appropriate status board for the Departure Controller.

Marshal Controller

Upon entering the carrier control area, inbound flights are normally turned over to the marshal controller for further clearance to the marshal pattern. The marshal controller must provide the inbound flight with the following:

1. Marshal instructions.
2. Steer to marshal (if required).
3. Type of recovery.
4. Ramp time
5. Altimeter setting and weather.
6. Expected final bearing.

The marshal controller must also insure that the following information has been provided each aircraft prior to commencing approach:

1. Expected approach time.
2. Final control frequency.
3. Type of approach.
4. Final bearing.
5. Time check.
6. Other pertinent data such as changes in weather conditions, altimeter setting, etc.

To reduce frequency congestion, items of general interest may be transmitted to blocks of aircraft rather than make repetitious broadcasts to individual aircraft.

Approach Controller

The Approach Controller assumes control of the inbound aircraft from the Marshal Controller. Circuit discipline is essential because two controllers and several aircraft are on each frequency. Two Approach Controllers are normally used, each with a separate frequency and with a final controller being on the same frequency. Each controller controls a block of four aircraft and passes control of each aircraft to the final controller when the aircraft reaches approximately 6 miles inbound (4 miles when using SPN-42). This procedure will vary when the radar equipment used provides a complete PAR approach, i.e., glidepath as well as azimuth, such as the SPN-42. In such cases the approach controllers (and final controllers) accept control of individual aircraft alternately.

In addition, the Approach Controller is responsible for the following:

1. Monitoring the aircrafts letdown and providing assistance as necessary on TACAN approaches.
2. Providing positive radar control during periods of TACAN failure.
3. Maintaining the proper interval between aircraft on all approaches.
4. Controlling the fouled deck holding pattern as necessary to maintain proper separation.
5. Insuring that approach control information on the approach status board is current and correct.

Final Controller

The Final Controller assumes positive control as soon as radar contact is established, normally at 6 miles from the ramp (4 miles on SPN-42). There are normally two Final Controllers, each of whom will be on a frequency with an Approach Controller. Since it is possible that a controller may have as many as four aircraft on final at one time, it is absolutely necessary that transmissions be kept to a minimum.

10698

Bolter/Waveoff Controller

The type of final approach radar installed will determine control responsibility for the bolter/waveoff pattern (e.g., those aircraft whose previous approaches did not result in an arrested landing).

This operator directs aircraft around the bolter/waveoff pattern to a point astern of the ship, from which another landing attempt can be made.

Close coordination is required with the approach controller to insure that aircraft approaching from the bolter/waveoff pattern are positioned properly with respect to other arriving aircraft.

Approach Status Board Keeper

The Approach Status Baord Keeper monitors the approach and final frequencies utilizing a split headset and insures that the latest information is displayed on the approach status board.

It is mandatory that personnel assigned duty as a status board keeper remember that the CCA officer and supervisor rely on the information displayed on the status boards to maintain the delicate teamwork balance required to make successful efficient approaches. Each operator also relies on the status board for pertinent information required for his respective position. Current and correct status boards provide CCA supervisors with a comprehensive display of the entire recovery, thereby eliminating interruption of operator personnel for progress reports.

Sound-Powered Telephone Talkers

The X1JG Sound-Powered Telephone Talker is assigned to provide for direct communications to Pri-Fly and LSO. The 2JG Sound-Powered Telephone Talker is assigned to receive and transmit general aircraft information to and from other offices concerned, such as CIC.

DEFINITIONS OF CATCC TERMS

Adivsory control. A form of Air Control in which the controlling agency monitors radar and radio contact with aircraft under its control and provides traffic advisories. Traffic separation is the responsibility of the individual pilot, with the assistance provided by the control agency.

Air operations. That section of the Operations Department responsible for coordinating all matters pertaining to air operations including the proper functioning of the CATCC.

Approach control. A control station in CATCC responsible for controlling air traffic from marshal until handoff to Primary Fly or the final controller.

Base recovery course (BRC). The ship's magnetic heading for the recovery of aircraft.

Bingo. An order to an aircraft to proceed immediately to a divert field. Bearing, distance and destination will be provided.

Bolter/waveoff control. A control station in CATCC responsible for all CCA bolter/waveoff traffic. The bolter/waveoff controller will vector assigned traffic under close control until responsibility is assumed by another control station.

Carrier air traffic control center (CATCC). The centralized agency responsible for the status keeping of all carrier air operations, and control of all airborne aircraft under the Operations Officer's cognizance except those being controlled by CIC.

Carrier control area. A circular airspace with a radius (50 miles for CVA's and 25 miles for CVS's) around the ship which extends upward from the surface to unlimited altitude and is under the cognizance of CATCC.

Carrier control zone. The airspace within a circular limit defined by 5 miles horizontal radius from the carrier, extending upward from the surface to and including 2,500 feet unless otherwise designated for special operations. The Air Officer exercises control over aircraft arriving and departing under visual flight rules and has clearance authority over all aircraft entering the zone.

CCA. Carrier controlled approach.

Center. A collective radio call prefixed by a ship's code name which is used in the same manner as the shore based counterpart.

Charlie. Signal for aircraft to land aboard the ship. A number suffix indicates time delay before landing.

Clara. A pilot transmission meaning he does not have the meatball in sight.

Close control. A form of air traffic control in which the controlling agency has radar and radio contact with the aircraft being controlled, and where specific assignments regarding heading and altitude are issued by the controller. While altitude separation is provided by pilots maintaining assigned altitude, lateral and time

separation is the responsibility of the Air Controller. Speed changes may be directed by the Air Controller.

Departure control. A control station in CATCC responsible for the orderly flow of assigned departure traffic.

Expected approach time (EAT). The future time at which an aircraft is cleared to depart inbound or penetrate from a preassigned fix. Aircraft depart and commence approach at assigned time if no further instructions are received.

Final bearing. The magnetic bearing assigned by CATCC for final approach. It is an extension of the landing area centerline.

Final control. A control station in CATCC responsible for controlling traffic in instrument conditions from acquisition until pilot reports "Meatball" or reaches approach minimums.

Inbound bearing. The magnetic heading assigned by CATCC to pilots descending directly to the carrier. It may be, but is not necessarily, the final bearing.

Inbound heading. The magnetic heading assigned by CATCC that will insure interception of the final bearing at a specific distance from the carrier.

Kilo. A pilot report indicating that the flight is ready to proceed on assigned mission.

Marshal. A bearing, distance, and altitude fix designated by CATCC from which pilots will orient holding and from which initial approach will commence.

Marshal control. A control station in CATCC responsible for the orderly flow of inbound traffic.

NOTE: For a detailed study of CATCC procedure, AC's should refer to the latest edition of the CVA/CVS NATOPS MANUAL.

FRESNEL LENS OPTICAL LANDING SYSTEM

The purpose of the lens system is to provide the pilot with a visual indication of his relative position with respect to a prescribed glide slope. This glide slope, as determined by the lens settings, is designed to bring the aircraft down to the deck, within the cross-deck pendant pattern, with a safe arresting hook clearance above the stern ramp of the carrier. Figure 13-25 illustrates the Fresnel lens unit.

A yellow bar of light is displayed over the full width of the lens box. The lens box may be considered a window through which the pilot views the bar of light. The bar of light appears as though it were located approximately 150 feet beyond the window. When viewed from anywhere on the prescribed glide slope, this bar of light (meatball) will appear in line with the green datum lights. The meatball will rise above the datum lights as the pilot rises above the glide slope, eventually sliding off the top of the lens box when the pilot is more than three-fourths of a degree above the glide slope. The same holds true as the pilot drops below the glide slope. The meatball will drop below the datum lights and finally slide off the bottom of the lens box. To sum up; when the meatball is high, (above the datum lights), the pilot is above the glide slope. When it is low the pilot is below the glide slope. In either case, the object is to lineup the meatball with the datum lights.

At great distances from the lens unit, it is difficult to distinguish the relative position of the meatball with respect to the datum lights, because the meatball can be distinguished before the green datum lights become visible. Pilots are therefore provided with a warning of low meatball by installing a RED lens in the bottom cell of the lens box. Thus, regardless of distance, when the meatball is RED instead of YELLOW, a pilot will know he is too low.

While controlling a CCA approach, it is the responsibility of the CCA final controller to position each aircraft on final as near to the centerline of the carrier angle deck as possible by giving right or left corrections. The final controller should have the aircraft on the courseline and holding a good heading prior to reaching a point 1 1/2 miles from the carrier.

Large azimuth corrections, to get back to the oncourse, should be avoided in the final stages of the approach. Carrier approaches are a critical phase of aircraft operation and erratic maneuvers at slow speeds usually prove ineffectual, if not disastrous.

The secret of a smoothly controlled approach is to assign large heading changes, as required, while the aircraft is at least 3 miles or more

1070710700

AC.212

Figure 13-25.—Fresnel lens unit.

from the ship. If this technique is used, only small corrections should be needed when the aircraft gets closer.

When the pilot has the meatball in sight and is prepared to complete the approach visually, he will transmit, MEATBALL. The controller ceases transmission and the pilot then adjusts his descent to put the meatball in line with the datum lights and makes any necessary azimuth corrections. The pilot continues to visually fly the meatball to an arrested landing.

PILOT LANDING AID TELEVISION (PLAT) SYSTEM

PLAT is a completely integrated system of electronic picture and sound recording designed to monitor and simultaneously record aircraft landing operations from approach through final touchdown, under both day and night conditions, and to immediately play back the recording for postflight analysis and evaluation.

The PLAT system consists of four television cameras. Two unmanned centerline cameras (one regular, one emergency), stabilized to the ship's optical landing system, pick up and follow aircraft through final approach and landing. Aircraft attitude and glide slope are displayed on picture monitors in combination with the output of a special effects camera focused on a data board carrying time, date, wind velocity, and aircraft landing speed. During the launch and the recovery, and after touchdown, the aircraft can be monitored by a fourth (manned) camera on the ship's island structure as it passes over the centerline cameras and the information is again displayed with the output of the data board camera. The entire operation is recorded on video tape at the same time it is monitored by the television cameras.

Television receivers are located at various places throughout the ship. There is a receiver in each pilot's readyroom, in air operations, in the CCA control room, and on the bridge.

In addition to the benefits afforded in the later study of a pilot's landing technique, PLAT is also helpful as a viewing aid for personnel (air operations and CCA) that previously were unable to view the flight deck activity. It reduces somewhat the sound-powered phone conversation. In the past, certain information had to be collected over the phone circuits that can now be seen on the television receiver.

RADAR PROCEDURE

Radar procedure contained herein pertains in most part to the ATC program ashore. Basic control procedure applies to all areas of radar air traffic control; however, detailed procedures for shipboard operations are contained in the CVA/CVS NATOPS MANUAL.

AC's assigned duty in a CCA or GCA crew receive specialized training at a Class C school

0070410701

and upon completion and qualification are assigned a Naval Enlisted Classification Code indicating their specialty within the Air Controlman general rating.

A radar controller must be personally satisfied that the radar presentation and the equipment performance are adequate for the service to be provided before attempting to provide such service.

Upon assuming responsibility for a control position, a controller should check radar alinement. This may be accomplished by assuring that the video map or map overlay in use is properly alined relative to the true geographic position, or by correlating a permanent target of known range and azimuth with the radar display. A target in each quadrant should be checked where possible. A brief check should again be made at various times throughout the watch to insure accuracy of the radar.

When radar mapping is not available, radar service is limited to separating identified aircraft targets, vectoring aircraft to intercept a PAR final approach course, and providing service in areas that insure no confliction with traffic on airways or other ATC areas of jurisdiction.

RADAR IDENTIFICATION

Positive radar identification must be established before radar service is provided. There are instances where radar separation may be applied between two aircraft when only one aircraft is radar identified. For example, this occurs when a radar identified aircraft is separated from an aircraft taking off that will be identified within 1 mile of the end of the takeoff runway. It also occurs when a radar identified aircraft is separated from an IFR aircraft not radar identified by maintaining radar separation from all primary and secondary radar targets.

Primary and secondary radar identification may be established by one of the following methods:

1. Observing a departing aircraft target within 1 mile of the end of the takeoff runway.

2. Observing a target whose position with respect to a fix displayed on a video map, map overlay, as a permanent echo, or an accurately determined visual reporting point, corresponds with a direct position report received from the aircraft, and the observed track is consistent with the reported heading or route of flight. If a TACAN/VORTAC is located within 6,000 feet of the radar antenna, it may be used as a reference fix for radar identification without being displayed on the video map or map overlay. When such situations exist, a pilot reported radial/distance may be correlated with the main bang for establishing radar contact.

3. Observing a target, make an identifying turn or turns of 30 degrees or more, provided that, except in the case of lost aircraft, it is determined that the aircraft is within radar coverage, and only one aircraft is observed making the turns.

When using secondary radar (SIF) to identify a target, one of the following methods may be used:

1. Request the pilot to activate the IDENT feature of the transponder and observe the identification display.

EXAMPLE: IDENT; or, SQUAWK ONE TWO ZERO ZERO AND IDENT.

2. Request the pilot to change to a specific code and then observe the target display change.

3. Request the pilot to change the transponder to STANDBY. After observing the target disappear for a sufficient number of scans to assure that loss of target resulted from placing the transponder in STANDBY, request the pilot to return the transponder to normal operation and observe the reappearance of the target.

EXAMPLE: SQUAWK STANDBY, then, SQUAWK ONE TWO ZERO ZERO.

Where circumstances are present to cause doubt as to target identification, more than one method of identification should be used.

If identification of a radar target becomes questionable due to ring-around, scope clutter, etc., immediate action should be taken to maintain identity, re-identify the aircraft, or terminate the radar service.

The pilot must be informed whenever radar identification with his aircraft is initially established or re-established after radar contact being lost or radar service being previously terminated. He must also be informed when radar contact is lost.

Whenever radar identification is established by means of identifying turns or radar beacon (SIF) procedure, the pilot should be advised of the aircraft's position. Position information need not be given when radar identification is established by position correlation or when a departing aircraft is observed within 1 mile of the end of the takeoff runway.

The pilot of an aircraft being provided radar service must be informed when the service is terminated except when any of the following conditions exist:

10701

10702

a. The aircraft conducts a visual approach.

b. Stage I, II, or III procedures (discussed later in this chapter) are employed.

c. The aircraft is vectored to the final approach course.

d. The aircraft conducts a radar approach.

NOTE: These exceptions allow reduction of transmission by eliminating the need to state the obvious to a pilot; for example, completion of a radar approach.

LOST COMMUNICATIONS

As soon as practicable after establishing identification, inform the pilot of the aircraft being vectored of the procedure to follow (proceed visually, execute a specified nonradar approach, or follow the missed approach procedure) if radio communications are lost for a specified time interval. This interval cannot be more than 1 minute during vectors to final approach.

RADAR VECTORS

A radar vector is a heading issued to an aircraft to provide navigational guidance by radar. IFR and VFR aircraft may be vectored within controlled airspace and special VFR aircraft may be vectored within control zones. An aircraft may be vectored outside controlled airspace only on request of a pilot. Radar advisories may be offered to the pilot of an aircraft operating within or outside of controlled airspace since an advisory is intended to assist pilots by offering advice or information and is not a clearance or instruction.

IFR and special VFR aircraft may be vectored when it is necessary for separation purposes, when required for noise abatement considerations, when an operational advantage to the pilot or controller exists, or when requested by a pilot. When separation from other aircraft is based on vectoring special VFR aircraft, a controller must consider the pilot's requirement to conduct flight clear of clouds with at least 1 mile flight visibility.

VFR aircraft, other than special VFR aircraft, may be vectored only when one of the following conditions exists:

1. The pilot requests a vector.

2. A controller suggests the vector and the pilot concurs.

3. A special program is established and vectoring service is advertised.

4. In the controller's judgment, a vector is necessary for safety.

Vectoring aircraft for the purpose of separation can only be done if the aircraft to be vectored is within the airspace for which the radar controller has control jurisdiction.

A controller must insure that an aircraft can be returned to its original route within radar coverage before providing radar vectors and should use one of the following vectoring methods:

1. Specify direction of turn and magnetic heading to be flown after completion of the turn.

EXAMPLE: TURN LEFT/RIGHT HEADING THREE FIVE ZERO.

2. Provide no-gyro vectors as follows:

a. Inform the pilot of the aircraft of the type of vector and the manner in which turns are to be made.

EXAMPLE: THIS WILL BE A NO-GYRO VECTOR; EXECUTE TURN INSTRUCTIONS ON RECEIPT.

b. Specify the direction of turn and when to stop the turn when issuing each turn instruction.

EXAMPLE: TURN RIGHT/LEFT. STOP TURN.

3. When the heading of the aircraft is not known and time does not permit obtaining it, specify, in group form, the number of degrees to turn and the direction of turn.

EXAMPLE: TURN THIRTY DEGREES LEFT/RIGHT.

4. Specify the magnetic heading to be flown.

EXAMPLE: FLY HEADING TWO SEVEN ZERO.

5. Specify that the present heading be maintained.

EXAMPLE: MAINTAIN PRESENT HEADING.

When an aircraft is vectored off a previously assigned nonradar route, the pilot should be informed of the purpose of the vector, including the airway, route, or point to which the aircraft is being vectored.

EXAMPLE: TURN RIGHT HEADING ZERO FIVE ZERO FOR VECTOR TO VICTOR THREE TWELVE, or FOR VECTOR TO RUNWAY THREE FIVE TRAFFIC PATTERN, etc.

An altitude to be maintained and all altitude restrictions should be issued to the pilot of such aircraft unless the aircraft is operating at an assigned en route altitude, or the aircraft is or

10703

will be climbing or descending unrestricted to the assigned en route altitude.

Radar navigational guidance must not be terminated until the aircraft being vectored is reestablished within the airspace to be protected for the airway or route being flown, on an assigned heading which will intercept the desired route within a reasonable distance, and the pilot of the aircraft is informed of his position.

EXAMPLE: OVER GEEDUNK TACAN, RESUME NORMAL NAVIGATION.

When an aircraft will be vectored through a previously assigned nonradar route, the pilot should be so informed and given the purpose of the vector.

Whenever an aircraft is observed in a position and on a track which will obviously cause it to deviate from its protected airspace, the pilot should be informed and if necessary the controller should assist the pilot to return the aircraft to the assigned protected airspace.

Whenever radar identification is established or lost, or radar service is terminated, the pilot of the aircraft must be informed.

After the pilot receives the statement that his aircraft is in RADAR CONTACT, he discontinues reporting over compulsory reporting points. The pilot will resume normal position reporting when a controller informs him RADAR CONTACT LOST, or RADAR SERVICE TERMINATED. If necessary, a controller may request a pilot to provide an estimate or report over a specific fix even though RADAR CONTACT has been established. Additionally, the controller may inform the pilot of such aircraft of his position with respect to a fix or route when required.

RADAR HANDOFF

Radar handoffs should be made along regularly used routes to the maximum extent practicable. A controller effects a handoff by physically pointing out the target to the receiving controller, or informing the receiving controller of the distance and bearing of the target from a fix or transfer point shown on both displays, and if appropriate, the radar beacon code assigned. The receiving controller may consider that the target being transferred is identified on his display when the transferring controller has pointed out the target physically, or the target is the only one observed which corresponds with the information furnished.

Communications should be transferred to the receiving controller before the aircraft being handed off enters his area unless previously coordinated otherwise. To the extent possible, the communications transfer should be initiated at the time of handoff.

A receiving controller may assume control of an aircraft being handed off only after it enters his area of responsibility unless specifically coordinated otherwise at the time of handoff. When a transferring controller transfers control of an aircraft by handoff before it leaves his area of responsibility, he must issue to, and coordinate with, the receiving controller any restrictions which may be necessary to separate the aircraft being handed off from other traffic in the transferring controller's area.

After a receiving controller accepts a handoff from another facility, he should confirm the identity of a nonbeacon target by advising the pilot of the aircraft's position. Alternatively, he may confirm the identity of a beacon target by observance of an IDENT, a code change, or a standby squawk, as appropriate. It is not necessary to require additional confirming transponder replies if one of these methods was used to remove doubt during the handoff. In either situation, the receiving controller should advise the pilot of RADAR CONTACT when appropriate after the handoff.

RADAR BEACON CODE ASSIGNMENT

Controllers with equipment capability must monitor the beacon codes assigned for use by aircraft operating within their areas of responsibility. Specific codes are assigned to indicate a particular type of aircraft operation. Some of the frequently used codes are listed as follows:

1. 1000—To aircraft which will climb to operate below FL 240, including VFR OTP.
2. 2000—To aircraft which will climb to operate at FL 240 or above, including VFR OTP.
3. 0100—To aircraft which will operate under tower en route control; may be assigned to aircraft receiving terminal VFR radar advisory service.
4. 1100—To IFR en route aircraft below FL 240.
5. 2100—To IFR en route aircraft at or above FL 240.

NOTE: 1100 or 2100, as appropriate, may be assigned at takeoff with prior coordination

60502 10704

with the facility concerned to eliminate the necessity of changing codes.

6. 0600—To aircraft below FL 240 operating VFR on top on an IFR clearance or which cancels IFR.

7. 0700—To aircraft at FL 240 or above, operating VFR on top on an IFR clearance or which cancels IFR.

8. 0400—To aircraft transferred to the destination approach controller.

9. 1400—To aircraft when issued descent clearance unless otherwise agreed upon between center and terminal controllers.

These codes may be considered as a basis from which the discrete coding procedure begins. Facilities or positions within a facility may be assigned a code not included herein by appropriate authority. With coordination between controllers concerned, various modifications of the basic procedure may be used when circumstances require. For more information, the AC should refer to the appropriate section of the TATC Handbook 7110.8 (Series).

Pilots of aircraft operating a transponder should be instructed to SQUAWK STANDBY when approximately 15 miles from destination if the transponder is no longer desired by the terminal controller. They may also be instructed to SQUAWK LOW when necessary to reduce clutter or ring-around, provided that the pilot is instructed to SQUAWK NORMAL as soon as possible after the problem is eliminated.

DEPARTING AIRCRAFT

Standard departure routes and channelized altitudes should be used for radar departures whenever practicable to reduce coordination. However, such procedure should not be used solely to provide for possible radar or communications failure.

When an aircraft is to be vectored immediately after takeoff, the initial heading to be flown should be assigned before takeoff.

If a radar beacon reply is required immediately after takeoff, the appropriate mode/code, and if necessary a low sensitivity setting, should be assigned before takeoff.

An IFR departure, or a missed approach aircraft, within 40 miles of the antenna site, may be vectored before it reaches the minimum altitude for IFR operations provided that one of the following conditions is met:

1. The aircraft is vectored to maintain at least 3 miles separation from prominent obstructions shown on the radarscope when the takeoff path is 3 miles or more from the obstruction.

2. The aircraft is vectored to increase lateral separation from such obstructions until the 3-mile minimum is achieved when the takeoff path is less than 3 miles from the obstruction.

ARRIVING AIRCRAFT

Successive arriving aircraft may be handed off with only radar separation if previously agreed to between facilities concerned and the following conditions are met:

1. The receiving controller establishes communication with the first aircraft before the pilot of a second aircraft, cleared to or over the same fix, is instructed to change to the receiving controllers frequency (unless an airport clearance limit is used).

2. The pilot of the first aircraft establishes communication with the receiving controller before it reaches the clearance limit fix.

3. The receiving controller does not delay the first aircraft at a fix to or over which a second aircraft is cleared.

Arriving aircraft may be vectored to intercept the final approach course of a precision approach. In such cases, the vectoring technique must allow for interception of the final approach course prior to reaching the point where interception of the glide slope is normally made.

If it becomes necessary to vector an aircraft through the final approach course of the approach the aircraft is executing, the pilot should be so informed. This will clarify your actions with the pilot and avoid confusion since the pilot is anticipating a turn inbound on final approach course and is naturally concerned when such instructions are not received as anticipated.

An arriving aircraft may be descended to minimum vectoring altitude, vectored to the VFR traffic pattern, instead of the final approach course, and cleared for a visual approach if the following conditions are met:

1. The reported ceiling is at least 500 feet above the minimum vectoring altitude and the visibility is at least 3 miles.

2. Radar separation must be provided from any preceding IFR aircraft until visual separation can be provided. (Visual separation may be applied even though the aircraft is outside the control zone when this procedure is used.)

3. The clearance for the visual approach is issued after the pilot reports sighting the air-

10705

port and the tower controller is advised of the aircraft's position where there is no preceding aircraft; or, when following a preceding aircraft, the clearance is issued after the pilot reports sighting the preceding aircraft, is instructed to follow it, and the tower controller is advised of the aircraft's position in the landing sequence.

Aircraft may be vectored simultaneously to the traffic pattern for more than one runway provided the following conditions are met:

1. Radar separation is maintained until the aircraft involved are cleared for a visual approach.
2. Traffic information is exchanged between all aircraft involved, irrespective of the runway being used.

Speed Adjustment

To avoid excessive vectoring and provide for orderly radar handoffs, a radar controller may request arriving aircraft to adjust speed. This procedure should not be applied as a substitute for good vectoring technique. Speed changes should not be requested of aircraft in the following situations:

1. Conducting a published penetration.
2. After an aircraft has been cleared for approach. However, when subsequent circumstances require additional spacing, a request for a speed adjustment would be preferable to S-turns or a discontinuance of approach.
3. After an aircraft has passed the approach gate on final (see appendix I for approach gate).

All speed adjustment requests should be expressed in terms of knots, based on indicated airspeed, using 10-knot increments or multiples thereof.

Consideration must be given to maximum speeds authorized by FAR 91 in particular airspace to insure that speed adjustment requests are within those limits. Requests requiring alternate decreases and increases should be avoided.

For more information on speed adjustment minima and limitations, refer to the appropriate section of TATC Handbook 7110.8 (Series).

ADDITIONAL RADAR SERVICES

Several types of service available through the use of radar may be provided pilots, such as observed traffic information. These services should be provided to the extent possible. Many factors, such as controller workload, limitations of the radar, communications congestion, etc., may preclude providing these services. The controller himself must determine if he is able to provide them.

Traffic Information

Traffic information should be issued to all IFR flights (unless omission is requested by the pilot or the aircraft is operating in positive controlled airspace), and to other than IFR flights when requested by the pilot.

Traffic information issued to radar identified aircraft must include the following items:

1. Azimuth from the aircraft in terms of the 12-hour clock.
2. Distance from the aircraft in miles.
3. Direction in which the traffic is proceeding.
4. Type of aircraft and altitude if known, or the relative speed of the traffic; i.e., slow or fast moving.

EXAMPLE: TRAFFIC, THREE O'CLOCK, WESTBOUND, SLOW MOVING.

Traffic information issued to aircraft that are not radar identified must include the following items:

1. Distance and direction with respect to a fix.
2. Direction in which the traffic is moving.
3. Type of aircraft and altitude if known, or the relative speed of the traffic.

EXAMPLE: TRAFFIC, SIX MILES SOUTH OF SNARE VOR, NORTH BOUND, C ONE FORTY ONE, FLIGHT LEVEL TWO ONE ZERO.

Radar separation is provided between the aircraft receiving traffic information and the observed traffic only if the pilot requests it, and the aircraft to be vectored is within airspace for which the controller has jurisdiction.

The pilot of a radar identified aircraft that reports he does not see the traffic as reported should be advised when the observed traffic is no longer a factor unless his aircraft is being vectored to provide separation from the traffic.

Whenever a controller observes a situation which, in his opinion, is likely to affect the safety of a radar identified aircraft, an advisory should be issued to the pilot.

When it becomes known that an aircraft not under radar control is at the same altitude and in the same general area as a radar controlled aircraft, the controller must take whatever ac-

10706

tion considered necessary to separate the aircraft concerned.

Weather and Chaff Information

Weather and chaff information, when applicable, should be issued by stating its position with respect to the aircraft or a fix, as is traffic information. A vector or alternate route to avoid such areas may be suggested as appropriate.

Bird Activity Information

Advisory information on pilot reported or radar observed and pilot verified bird activity should be issued. The position, and, if known, the size or species of the birds and their course of flight and altitude must be included in the advisory.

Surveillance of Outer Fix Holding

Radar surveillance of outer fix holding pattern airspace areas shown on the radarscope should be provided when aircraft are being held there. If a controller should detect an aircraft straying outside the area, he should assist the pilot to return it to the assigned airspace.

Pilot Requested
Navigational Guidance

Navigational guidance requested by pilots should be limited to vectors within a controller's particular area of responsibility unless such action can be coordinated with a subsequent receiving controller or facility.

Navigational guidance may be provided as a radar advisory to aircraft outside of controlled airspace when requested by the pilot.

TERMINAL RADAR SERVICE

The FAA has established a national program for terminal radar facilities. The extent and complexity of the service provided is varied depending on the facility and whether or not a formal, approved program has been established for that facility. The variance is described in STAGES, i.e., STAGE I, II, or III. This service is in addition to the "Additional Radar Services" previously described.

Stage I service procedure is applicable to all approach control facilities utilizing radar and includes the following radar controller actions when arriving VFR aircraft are handled by approach control:

1. Wind and runway information is issued unless pilots indicate they already have this information.
2. Traffic information is issued on a workload permitting basis.
3. The time or place at which the pilot is to contact the tower for further landing information is specified.
4. Vectoring service is provided if the pilot requests, if the controller suggests it and the pilot concurs, or if controller judgment deems it necessary for safety.
5. When initial contact is made with the tower, it may be suggested that the aircraft contact approach control for landing and traffic information.

Stage II service is only applicable at facilities where a formal, approved program has been established for this purpose. It is in addition to Stage I service and generally includes identification, holding, sequencing aircraft in the landing pattern including IFR traffic, vectors to landing patterns for more than one runway, transfer of control procedure between the local controller and approach controller, missed approach aircraft resequencing, and departure information for VFR aircraft.

Stage III service is only applicable within a designated Terminal Radar Service Area (TRSA) where a program has been established for this purpose. It is in addition to Stage II service and in essence is positive control of aircraft that operate within the TRSA.

For detailed procedure concerning Stage II and III service refer to the applicable section of TATC Handbook 7110.8 (Series).

EMERGENCY RADAR
FLIGHT PATTERNS

Radar controllers must be on the alert for emergency radar flight patterns executed by pilots who experience two-way communications failure and must render assistance to the extent possible to any aircraft determined by this method to be experiencing an emergency. If an emergency radar flight pattern is observed by a controller in a facility other than a center, the appropriate center must then be notified immediately. The center is then responsible for coordinating action pertinent to the emergency.

10707

This list, however, should not be construed as being all inclusive.

The indicator or presentation system accepts the radar data such as video pulses, range-marker voltages, sawtooth timing waves, and presents them in a visual display on the cathode-ray tubes. An indicator assembly contains the cathode-ray tube and various electronic circuits necessary for presenting the desired information on the CRT. These circuits include video amplifiers, clampers, and the controls for adjusting the brilliance and focus of the visual pattern.

Two general types of presentation are used in radar indicators—deflection-modulated and intensity-modulated displays. In the deflection method, the video pulse causes a momentary deflection of the cathode-ray electron beam and produces a pip in the trace to indicate a target echo. In the intensity method, the video signal is applied to the element of the CRT which controls the intensity of the electron beam, and the resulting target image is a bright spot of light. Three types of intensity presentations are shown in figure 15-8. A detailed discussion of indicators is made in chapter 17 of this training course.

MONOPULSE

Monopulse is a simultaneous scanning system capable of obtaining the range, bearing, and elevation of a target from a single pulse. Hence, the name mono (one) pulse. In the monopulse system, the radar radiates into space a single beam whose axis coincide with the antenna axis. Normally, with a single beam fixed with respect to the antenna, a target could move a substantial distance from the antenna's axis before the radar's tracking system would detect a displacement and react.

Figure 15-8.—Scan presentation.

The emergency radar flight patterns designed to alert radar systems are as follows:

1. If the aircraft radio transmitter is inoperative but the receiver is operative, the aircraft is flown in a triangular pattern to the RIGHT. The heading for each side of this pattern is followed for 2 minutes (1 minute for turbojet aircraft). After completion of at least two such patterns, the aircraft is returned to its original course. The pattern is then repeated at 20-minute intervals. In these circumstances, pilots ordinarily guard emergency radiofrequencies (121.5 or 243.0 MHz).

2. If the aircraft transmitter and receiver are both inoperative, the aircraft is flown in a triangular pattern to the LEFT in the same manner as above. (See fig. 13-26.)

3. If the pilot of a distressed aircraft is unable to communicate by radio or radar beacon and is in urgent need of assistance, he may make a series of four chaff drops followed by a series of 360-degree turns. (See fig. 13-26.) The pilot will attempt to dispense four chaff bundles with a 2-mile interval between each drop and will then fly approximately 2 miles, make a 360-degree turn to the left and repeat the 2-mile legs and 360-degree turns until a series of 4 turns have been completed.

NOTE: Any unscheduled chaff observed on radar should be suspected as a possible emergency since radar limitations may preclude detection of the entire emergency pattern.

SAFETY PRECAUTIONS

AC's in the performance of the majority of the duties of their rating, are operating electric or electronic equipment. They may also be called upon to assist maintenance personnel with that portion of preventive maintenance which requires the equipment to be kept free of potential problem-causing dust and dirt. There are many dangers to personnel who operate and maintain electronic equipment. Among the possible dangers in the Air Controlman's work are high voltages, breakage of cathode-ray tubes, volatile liquids, electrical fires, and noxious gases. Because of these dangers the Air Controlman should regard the formation of safe and intelligent work habits as being equally as important as development of the technical knowledges and skills of the Air Controlman rating.

AC. 213

Figure 13-26.—Emergency radar flight patterns.

10708

GENERAL SAFETY PRECAUTIONS IN ELECTRONIC MAINTENANCE

Because of the possibility of injury to personnel, the danger of fire, and possible damage to material, all repair and maintenance work on both electronic and electrical equipment should be performed only by duly authorized and assigned persons.

When any electronic equipment is overhauled or worked on, and there is danger of personnel coming into contact with it, always tag the equipment to show that work is being performed. After the work has been completed, the tag should be removed by the same person who placed it on the equipment.

Safety devices such as interlocks, overload relays, and fuses should never be altered or disconnected except for replacement. Fuses should be removed and replaced only after the circuit has been completely de-energized. When a fuse blows, it should be replaced with a fuse of the same current rating. When possible, the circuit should be carefully checked by maintenance personnel before making any replacement since the burned-out fuse is often the result of a faulty circuit.

High Voltage Precautions

Personnel should never work alone near high voltage equipment. Tools and equipment containing metal parts, such as brushes and brooms, should not be used in any area within 4 feet of high voltage circuits or any electric wiring having exposed surfaces. The handles of all metal tools, such as pliers and cutters, should be covered with rubber insulating tape. (The use of plastic or cambric sleeving or of friction tape alone for this purpose is prohibited.)

Before a worker touches a capacitor which is connected to a deenergized circuit, or which is disconnected entirely, he should short-circuit the terminals to make sure that the capacitor is completely discharged. Grounded shorting prods should be permanently attached to workbenches where radar equipment and other types of electronic devices are regularly serviced.

Do not work on any type of electrical apparatus with wet hands or while wearing wet clothing, and do not wear loose clothing. The use of thinsoled shoes with metal plates or hobnails is prohibited. Safety shoes with nonconducting soles should be worn if available. Flammable articles, such as celluloid cap visors, should not be worn.

When working on electronic or electrical equipment, personnel should first remove all rings, wristwatches, bracelets, and similar metal items. Care should be taken that the clothing does not contain exposed zippers, metal buttons, or any type of metal fastener.

Warning signs and suitable guards should be provided to prevent personnel from coming into accidental contact with high voltages.

Transmitter adjustments should not be made while the equipment is energized unless the adjustments can be accomplished from the front control panel. Similar precautions should be taken with oscilloscope circuits, which employ voltages corresponding to those used in transmitting equipment.

Energized Circuits

Insofar as is practicable, repair work on energized circuits should not be undertaken. When repairs on energized operating equipment must be made because of emergency conditions, or when such repairs are considered to be essential, the work should be done only by experienced personnel. Every known safety precaution should be carefully observed. Ample light for good illumination should be provided; and the worker should be insulated from the ground with some suitable nonconducting material such as several layers of dry canvas, dry wood, or a rubber mat of approved construction. The worker should, if possible, use only one hand in accomplishing the necessary repairs. Helpers should be stationed near the main power source or circuit breaker so that the equipment can be deenergized immediately in case of emergency. A man qualified in first aid for electrical shocks should stand by during the entire period of the repair.

Volatile Liquids

Volatile liquids such as insulating varnish, lacquer, turpentine, and kerosene are dangerous when used near electronic equipment which is operating because of igniting the fumes by sparks. When these liquids are used in compartments containing nonoperating equipment, be sure that there is sufficient ventilation to avoid an accumulation of fumes and that all fumes are cleared before the equipment is energized.

10709 TO308

Alcohol should never be used for cleaning in locations where a spark is possible. Neither should carbon tetrachloride be employed as a cleaning agent. Unlike alcohol, the use of carbon tetrachloride does not create a fire hazard; however, it is dangerous because of the injurious effects of breathing its vapor. The careless use of carbon tetrachloride may result in headache, dizziness, and nausea. If a sufficient amount of these fumes are breathed (as might happen in poorly ventilated compartments), the effect will be loss of consciousness or even death. For these reasons, the use of carbon tetrachloride as a solvent or cleaner has been specifically prohibited in Navy maintenance operations. When cleaning electrical or electronic equipments or parts, always use the new approved cleaning agent trichlorethylene.

Electrical Fires

In case of electrical fire, the following steps should be taken:

1. Deenergize the circuit.
2. Call the Fire Department.
3. Control or extinguish the fire, using the correct type of fire extinguisher, if at all possible.
4. Report the fire to the appropriate authority.

For combating electrical fires, use a CO_2 (carbon dioxide) fire extinguisher and direct it toward the base of the flame. Carbon tetrachloride should never be used for fighting fires since it changes to phosgene (a deadly gas) upon contact with hot metal. Even in open air this gas creates a hazardous condition. The application of water to electrical fires is also dangerous; and foam type fire extinguishers should not be used since the foam is electrically conductive. In case of cable fires in which the inner layers of insulations, or insulation covered by armor, are burning, the only positive method of preventing the fire from running the length of the cable is to cut the cable and separate the two ends.

Precautions in Handling Cathode-Ray Tubes

The trend toward the use of large cathode-ray tubes has increased the dangers of implosions, or collapse of the glass tube, as a result of atmospheric pressure. The tubes are not dangerous if properly handled; but if they are struck, dropped, or handled carelessly in any way, they can very well become an instrument of severe injury or death.

The following precautions should be taken for the protection of personnel:

1. Wear goggles to protect the eyes from flying glass particles which result from implosion due to fracture of the envelope. The goggles should be of the type which provide side and front protection and which have clear lenses that can stand a rigid impact test.
2. Wear suitable gloves to protect the hands.
3. Be sure that no part of the body is directly exposed to possible glass splinters caused by implosion. Also remember that the coating on some tubes is poisonous if absorbed into the bloodstream.
4. Take care of the tube by not exposing it to possible damage. When a new tube is needed, remove it from the packing box with caution, taking care not to strike or scratch the envelope. Insert the tube into the equipment socket cautiously, using only moderate pressure. Do not jiggle the tube. Use these same precautions when removing the tube from the equipment.

When the tube must be set down, it is important that the face be placed on a clean, soft padding. Do not stand directly in front of the face, because accidental implosion may cause it to be propelled directly forward with a velocity sufficient to cause severe injury.

TREATMENT FOR ELECTRICAL SHOCK

The greatest hazard around electrical and electronic equipment is the danger of electrical shock. Some very important things to remember when treating a victim for electrical shock are as follows:

1. Deenergize the circuit or release the victim from contact. Use caution, or you too may become a victim.
2. Begin artificial respiration IMMEDIATELY but only if the victim is not breathing. (Use the mouth-to-mouth method if at all possible.)
3. Keep the victim quiet after normal breathing is resumed.
4. Keep the victim lying down, head slightly lower than the feet. Keep him warm, but do not overheat him.

For a more detailed coverage of first aid methods, study Standard First Aid Training Course, NavPers 10081 (Series).

10710

CHAPTER 14

PUBLICATIONS, LOGS, AND RECORDS

Regardless of the segment of the air traffic control that you, as an Air Controlman, may be assigned, a knowledge and effective use of the various publications and catalogs associated with the field of air traffic control are extremely important. In addition, the Air Controlman must have a working knowledge of the maintenance of logs, records, reports, and forms used in this field.

It would be impractical to list and discuss all the publications, records, reports, logs, and forms that have a direct bearing on the Air Controlman in the course of this chapter. Therefore, only those most frequently used in the daily routine are discussed.

FAA PUBLICATIONS

AIRMAN'S INFORMATION MANUAL

The Airman's Information Manual has been designed as a pilot's operational manual for use primarily within the conterminous United States. All AC's should be familiar with this manual for ready reference when assisting pilots. Use of the Airman's Information Manual is part of the practical test for a Senior Rating in accordance with FAR Part 65. The manual is divided into three parts, each of which is described in the following paragraphs.

Part 1, Basic Flight Manual and ATC Procedures

This part is issued quarterly and contains basic fundamentals required to fly in the national airspace system; adverse factors affecting safety of flight; health and medical facts of interest to pilots; ATC information affecting rules, regulations, and procedures; a glossary of aeronautical terms; U.S. entry and departure procedures, including airports of entry and landing rights airports; Air Defense Identification Zones (ADIZ's); designated mountainous areas; SCATANA, and emergency procedures.

Part 2, Airport Directory

This part is issued semiannually and contains a directory of airports, seaplane bases, and heliports in the conterminous U.S., Puerto Rico, and the Virgin Islands which are available for transient civil use. It includes all of their facilities and services, except communications, in codified form. Those airports with communications are also listed in Part 3, which reflects their radio facilities. A list of new and permanently closed airports which updates this part is contained in Part 3.

Included, also, is a list of selected commercial braodcast stations of 100 watts or more of power.

Parts 3 and 3A, Operational Data and NOTAM's

Part 3 is issued every 28 days and contains a master index covering all parts of the Airman's Information Manual; an airport/facility directory containing a list of all major airports with communications; a tabulation of air navaids and their assigned frequencies; parachute jump areas; preferred routes; standard instrument departures (SID's); substitute route structures; a sectional chart bulletin, which updates sectional charts cumulatively; restrictions to enroute navaids; VOR receiver checkpoints; special, general, and area notices; a tabulation of new and permanently closed airports, which updates Part 2; and Oil Burner Routes.

Part 3A is issued every 14 days and contains NOTAM's considered essential to the safety of flight as well as supplemental data to Part 3.

10711

LOCATION IDENTIFIERS HANDBOOK 7350.1 (SERIES)

A location identifier is a three-letter or other code suggesting, whenever practicable, the location name of the place it represents. Usually the first letter of the code is the initial letter of the location name. A code with the initial letter of the location name is not always assignable because of the large number of assigned codes. All three-letter identifiers assigned to Navy and Marine Corps air stations begin with the letter N.

This handbook incorporates all authorized three-letter location identifier assignments worldwide, the Canadian Government location identifier assignments, and special use assignments within the United States and areas under its jurisdiction.

CONTRACTIONS HANDBOOK 7340.1 (SERIES)

This handbook contains the approved word and phrase contractions used by personnel of FAA and other agencies that provide air traffic control, communications, weather, charting and associated services.

A contraction is a word or phrase represented in shortened form for the purpose of brevity. Contractions are developed by omitting letters, sounds, or syllables from words or phrases. They save space on telegraphic circuits, charts, reports, etc. Three-letter contractions that might conflict with location identifiers are always avoided.

The more common contractions used in telegraphic communications can be easily and quickly memorized. However, the entire list of contractions is so long that the manual must be referred to quite frequently.

TERMINAL AIR TRAFFIC CONTROL HANDBOOK 7110.8 (SERIES)

This handbook prescribes air traffic control procedures and phraseology for use by personnel providing terminal air traffic control services. It is one of the air traffic control manuals referred to in FAR Part 65. Controllers are required to be familiar with the provisions of this handbook which pertain to their operational responsibility and to exercise their best judgment if they encounter situations not covered by it.

OpNav Instruction 3710.7 (Series) directs that the procedures contained in this handbook be used by U.S. Navy shore activities when performing air traffic control functions.

EN ROUTE AIR TRAFFIC CONTROL HANDBOOK 7110.9 (SERIES)

This handbook prescribes air traffic control procedures and phraseology for use by personnel providing en route air traffic control services.

Should your facility operate in an en route capacity, this manual should be referred to for procedures.

FLIGHT SERVICES HANDBOOK 7110.10 (SERIES)

This handbook consists of two parts. Part I, the basic part, prescribes procedures and phraseology for use by personnel providing flight assistance and communications services. Part II, the teletypewriter portion, includes services A and B teleypewriter operating procedures, pertinent International Teletypewriter Procedures, and the conterminous U.S. Service A Weather Schedules.

This handbook is primarily for Flight Service Specialists at FAA FSS's. However, certain portions contain information of use to the Navy AC that is not found in the Terminal Air Traffic Control Handbook. Of particular interest is Chapter 8, Flight Handling. This chapter describes the flight plan handling of military flight plans via FAA communications systems, and what action is taken when a flight is overdue or missing.

CERTIFICATION AND RATING HANDBOOK 7220.6 (SERIES)

This handbook governs the certification and rating of FAA Air Traffic Service Specialists and civil personnel engaged in air traffic control. It also governs those military and foreign national personnel who participate in the Air Traffic Service certification and rating program.

ADVISORY CIRCULAR

FAA issues advisory circulars to inform the aviation public in a systematic way of nonregulartory material previously issued in a wide variety of manuals, circular letters, aviation

10712

safety releases, etc. Advisory circulars are issued in a numbered-subject system, corresponding to the subject areas in the Federal Aviation Regulations. Persons who want to be placed on the mailing list for circulars should write to: Federal Aviation Administration, Distribution Section, HQ-438, Washington, D.C. 20553 and specify the subject matter desired.

FEDERAL METEOROLOGICAL HANDBOOK #1 SURFACE OBSERVATIONS

This handbook is promulgated within the Navy as NavAir 50-1D-1. It has been approved by appropriate personnel of the Departments of Commerce, Defense, and Transportation.

The handbook describes weather elements and how they are observed. The latter part of the handbook is devoted to types of observations, pilot's reports, and the determination, coding requirements, and dissemination of weather reports.

FLIGHT INFORMATION PUBLICATIONS

Flight information publications (FLIP) consist of that textual or graphic information required to plan and conduct a flight and accomplish a landing under varying weather conditions. Emphasis is on information required for navigation under IFR conditions although not confined to that alone. Generally, the publications are divided into the categories of use; i.e., the planning, en route, and terminal phases of flight; and the publications are tailored to these uses. A further breakdown, high and low altitude, results from differences in operational capabilities of jet versus conventional aircraft.

FLIP, PLANNING

The FLIP, Planning, was designed primarily for desk use and not for carrying in the aircraft. A complete FLIP, Planning, for the entire area of coverage will be composed of sections I through IV, as described in the following paragraphs of this section. A publications cycle (listed in Section I) is established to keep all information current. All sections may be revised between publication dates established by issuing replacement pages or a Planning Change Notice (PCN) on an "as required" basis. PCN's should be filed in front of the appropriate section.

A quarterly check list which spans the entire FLIP, Planning, is issued to holders of the publication as an additional means to determine that information is current.

The FLIP, Planning, does not contain all the information published elsewhere which may be needed in planning a flight. Planning charts, en route charts and supplements, and instrument letdown procedures must be consulted, as well as NOTAM files. In planning for international flights, reference must also be made to the Foreign Clearance Guide.

Section I, General Information

This section contains general information on all FLIP's, a list of FLIP and NOTAM abbreviations, the ICAO NOTAM code, conversion tables, sunrise and sunset tables, and an area of coverage chart.

Section II, Planning Data and Procedures

This section contains planning and procedure information for a specific geographic area including an index for aeronautical information, flight plans, clearances, etc.

Only the appropriate section II is included in an individual FLIP, Planning, as determined by the geographical area of coverage chart on the back cover of section I. For example, a station in the U.S. would have section II, Continental U.S. and Alaska; a station in the Pacific would have section II, Pacific, Australasia, and Antarctica.

Section IIA, Military Training Routes United States

This section is published primarily for flight planning and contains detailed data covering VFR and IFR/VFR Oil Burner Routes, VFR low altitude high speed training routes, Heavy Wagon low level routes and low and high altitude refueling tracks.

Accompanying charts (6 charts on 3 sheets) contain graphic descriptions of low altitude high speed training routes.

10713

Section IIB, Special Use Airspace

This section includes a tabulation of all Prohibited, Restricted, Danger, Warning, and Alert Areas, Intensive Student Jet Training Areas, Military Training Areas, and known Parachute Jumping Areas.

Section III, International Rules and Procedures

This section is provided for use in all areas of the world, and will be the same in each FLIP, Planning. It contains such detail as the following: Procedures covering international flights; international procedure charts showing ICAO (International Civil Aviation Organization) FIR (Flight Information Region) boundaries; Area Control Centers (ACC's); world wide altimeter setting procedures; regional VOLMET (ICAO abbreviation for meteorological information for aircraft in flight) plans; communications procedures; and emergency signals.

Section IV, Regulations

This section contains a list of regulations recommended to be inserted by the operations officer for reference by aircrew personnel. One list is issued for use in each FLIP, Planning, worldwide; this also lists, however, the regulations which are pertinent to any specific area.

IFR WALL PLANNING CHART—LOW ALTITUDE—U.S.

The IFR Wall Planning Chart consists of two sheets. It covers East and West U.S. and contains required information for preliminary flight planning. Its publication cycle is concurrent with the FLIP en route low altitude charts for the U.S.

There are also FLIP Planning Charts for both low and high altitude available for Europe and North Africa.

EN ROUTE AND TERMINAL PUBLICATIONS

FLIP en route and terminal publications are designed to provide airway structure, radio navigation, letdown, approach, and landing information for use during the in-flight phase of IFR operations. The FLIP En Route Supplement supports these publications with supplemental aerodrome, facility, communication, and procedural information. En route and terminal publications are available for all areas of the world, but only those applicable to the U.S. are discussed herein. AC's should refer to FLIP Planning Section I, or the publications themselves, for more detailed information.

Standard Instrument Departures (SID)

SID charts are published either as individual charts or as a bound booklet containing departure air traffic control instructions in a pictorial form, for departure from an individual aerodrome. Revisions are issued as required.

FLIP En Route Low Altitude—U.S.

These charts portray the airway system and related data required for IFR operation at altitudes below 18,000 MSL. Twenty-six variable scale charts are printed on 13 sheets, L-1 through L-26, covering the entire U.S. An additional sheet, containing charts L-27 and L-28, which duplicate data shown on L-20, L-22, L-24, and L-25, is available for those who frequently plan flights north and south along the east coast within the area of coverage.

The effective date and the expiration date are shown on the cover of each item. Major changes to the airway structure and procedures are scheduled by the FAA to become effective on a specific date, once every 4 weeks. Charts are revised accordingly and show the date this information is effective. Charts, therefore, should not be used prior to the effective date. Other information, such as frequencies, hours of operation, etc., is not scheduled and changes occur daily. Action is taken to update this data during the revision cycle, but it has to be terminated 15 days before the projected effective date of the issue under revision to permit printing and timely distribution to users. NOTAM's must be consulted for latest information on data changing after the cutoff date and during the life of the current charts. These charts are published every 4 weeks.

FLIP Area Charts—U.S.

These charts portray the airway system and related data required for IFR operations in selected terminal areas at altitudes below 18,000

61504 10714

MSL. Ten variable scale charts are printed on six sheets and are published every 4 weeks.

FLIP En Route High Altitude—U.S.

These charts portray the jet route system and related data required for IFR operations at and above flight level 180. Four constant scale charts are printed on two sheets. These charts may be assembled to form a wall planning chart for high altitude. They are published every 4 weeks.

FLIP En Route IFR Supplement—U.S.

This supplement is a bound booklet containing an alphabetical listing of all IFR aerodromes, integrated with an alphabetical listing of all navaids and ARTCC facilities. Also published are brief presentations of such items as ADIZ, direction finding, IFR emregency procedure, position reporting, two-way radio failure, and other information. It is published every 4 weeks.

FLIP En Route VFR Supplement—U.S.

This supplement is a bound booklet containing an alphabetical listing of selected VFR aerodromes and cross-references to IFR aerodromes as published in the IFR supplement. Also included are city/aerodrome cross-referency listings, VFR special notices, and visual air/ground emergency procedures. It is published every 12 weeks.

Military Aviation Notices (MAN's) are issued as required for the purpose of updating and correcting this supplement. All MAN's are numbered consecutively beginning each calendar year, and those published during the effective time of the VFR supplement should be attached to the inside front cover so that all significant changes are readily available.

FLIP Terminal High Altitude—U.S.

These publications consist of four bound booklets, each covering a certain geographic area of the U.S. They contain instrument approach procedures for high performance aircraft. Transitional information from the jet route structure to the terminal facility has been added to charts covering the U.S. They are published every 4 weeks.

FLIP Terminal Low Altitude—U.S.

These publications consist of nine bound booklets, each covering a certain geographic area of the U.S. They contain low altitude instrument approach procedures. They are published every 4 weeks.

FLIP Terminal Aerodrome Sketches—U.S.

This publication is a bound booklet containing IFR and VFR aerodrome sketches arranged in alphabetical order by aerodrome name. Sketches are designed as an aid to visual identification of aerodromes. They are published every 16 weeks.

FOREIGN CLEARANCE GUIDE

The Foreign Clearance Guide is a group of bound booklets, including a general information section. The Foreign Clearance Guide is the official publication for disseminating USAF worldwide foreign clearance requirements and information on personnel travel; aircraft movement to, from, and between foreign areas; and transport of material aboard aircraft. It is also used by the Navy and Army. Revised area booklets and general information sections are issued on a semiannual and quarterly basis. The Foreign Clearance Guide Change Notices (FCCN) are issued monthly. These notices contain a cumulative listing of all permanent and temporary changes not yet incorporated in the booklets. A classified supplement is issued quarterly. Teletype Interim Changes Notices (ICN) are dispatched as required to selected addressees who require immediate notification of changes to the Guide.

DOD CATALOG OF AERONAUTICAL CHARTS AND FLIGHT INFORMATUON PUBLICATIONS

This catalog is a looseleaf publication, which provides a complete listing of DOD/USN/USAF aeronautical charts, flight information publications, and miscellaneous items available to DOD users. It includes indexes of available items, together with descriptive information for each item and requisitioning procedures. In this publication will be found added detail regarding publications produced by other agencies, and

10715

available for DOD usage (such as ICAO documents). A classified supplement is also available.

DOD AERONAUTICAL CHART UPDATING MANUAL (CHUM)

This manual is published monthly to provide a cumulative listing of significant additions or corrections to be considered when using current editions of USAF/USN published aeronautical charts. It is used to up date charts other than those contained in the FLIP series and contains notices of special interest to aeronautical chart users. It should be made available to flight crews during preflight planning.

DOD AERONAUTICAL CHART BULLETIN

This is also a monthly publication to inform activities of the availability of new aeronautical charts and publications, new additions of previously published charts, discontinued charts, and notices of special interest to requisitioners of aeronautical charts. The chart bulletin may be placed in the front of the DOD Catalog of Aeronautical Charts and Flight Information Publications for ready reference during preflight planning.

New issues of the Bulletin do not make prior issues obsolete. The most recent six issues of the Bulletin become obsolete by each subsequent publication of the DOD Aeronautical Chart Bulletin Digest.

DOD AERONAUTICAL CHART BULLETIN DIGEST

This bulletin is published semiannually to provide activities with a listing of current editions of charts on issue. This information is provided so a check can be made of charts on hand to assure that editions carried are up to date.

NAVY PUBLICATIONS

MEMORANDUM FOR AVIATORS

This publication is published when necessary to disseminate urgent information or information of a temporary nature concerning dangers and aids to navigation.

DIRECTIVES

Directives pertinent to policies, operating procedure, etc., are set forth in the form of instructions and notices by authorities in the chain of command. Each activity maintains a current file of those instructions and notices directly related to air traffic control. AC's should familiarize themselves with all such directives which in any way pertain to their rating.

GENERAL FLIGHT AND OPERATING INSTRUCTIONS, OPNAV 3710.7 (SERIES)

This manual prescribes general flight and operating instructions and procedures applicable to the operation of naval aircraft and related activities. Chapters 5 and 6 are of direct interest to the AC 3 & 2 and chapter 11 to a lesser extent. AC's should familiarize themselves with the appropriate parts of this manual since it is applicable to the naval establishment and compliance with the procedures is mandatory.

CVA/CVS NAVAL AIR TRAINING AND OPERATING PROCEDURES STANDARDIZATION (NATOPS) MANUAL

This manual is published under the authority of the Chief of Naval Operations as part of the NATOPS program. Extensive coverage of CCA operating procedures and responsibilities is included.

AIR OPERATIONS MANUAL

OpNav Instruction 3710.7 (Series) sets forth a basic outline for preparing standard Air Operations Manuals. These manuals are prepared locally under the supervision of the commanding officers of the air stations and they must be signed by the commanding officers.

These manuals contain specific information and instructions for the control of aircraft and aircraft-handling equipment in use at the field, instructions relating to transient aircraft and personnel, and procedures for crash and rescue. The Operations Manual should be read and understood by all Air Controlmen soon after reporting to a new duty station so as to become familiar with types of local operations and facilities.

VT01 10716

TECHNICAL MANUALS

In all phases of work, the Air Controlman operates different types of electronic equipment designed for use in air traffic control. To efficiently and effectively use these different types of equipment, the Air Controlman must know where to find information describing proper equipment operating procedures. With such technical assistance and instructions from experienced personnel, the time required to become familiar with a particular piece of equipment may be shortened. Equipment familiarity is necessary to be a good controller since one must have confidence in his ability to operate and in the performance of the equipment.

There is a technical manual published for each electronic equipment system. This manual should be available in the local ground electronics shop. One chapter in each manual is devoted to operation. Such chapters contain information necessary for operating personnel to start, operate, and stop the equipment.

RECORDS AND REPORTS

While performing duties in the different fields of the rating, certain records, reports, operating logs, and equipment logs are maintained by the Air Controlman. With the exception of a few, there is no standard authorized format to be employed in the maintenance of these records. However, the general contents of many are the same. The reports, records, and logs discussed in this chapter are the ones that are maintained by control towers, operations offices, and radar facilities.

CONTROL TOWER WATCH STANDER'S LOG

This record or log is kept from watch to watch in all Navy control towers. It contains all of the pertinent data accumulated during each watch performed in the control tower. A partial listing of the data that is entered indicates status of equipment, check of communications, status of airport lighting facilities, runway or runways in use, and any other information deemed necessary by the control tower officer, chief, or section leader of the tower concerned. The items listed above are not standard throughout the Navy, but they serve to indicate certain items which should be contained in the control tower log.

At many facilities it is an accepted practice to make an entry in the tower log of the weather when the watch is changed and at anytime the field goes from VFR to IFR weather conditions or vice versa.

Additionally, many facilities log entries of emergencies and crashes in the tower log in red ink. All details of such incidents with the associated time of occurrence are included for later reference.

DAILY AND MONTHLY TRAFFIC COUNTS

To facilitate completion of certain reports required of the ATC Division, a daily and monthly tabulation of aircraft operations is necessary. One system commonly used is posting flight progress strips (described in chapter 3) on each operation. At midnight a traffic count is made from the strips and subsequently a monthly count is made. These strips are kept for 3 months before they are destroyed. If any strip contains information on an aircraft involved in an accident or emergency, it is kept for a longer period of time.

This same basic procedure may also be used in flight clearance and at the approach control position in a RATCC; however, different data is required at these positions.

FLIGHT CLEARANCE OFFICE LOGS AND RECORDS

The flight clearance office is the central point for processing aircraft movement and related messages. This office must maintain various records, logs, and files connected with air operations. Examples of information on file include SCATANA action forms, Facility License for civilian concerns, VIP notification procedure, telephone numbers of other departments that furnish services required by transient aircrews, FLIP's, and FAA publications required in daily functions. Examples of records kept are flight plans (DD 175's) filed with flight clearance, flight progress strips, and teletype messages.

Duty Dispatcher's Log

The duty dispatcher's log is maintained at the clearance desk from watch to watch. Personnel assuming the watch enter in the log

10717

To track a moving target, an error signal is necessary. Error signals are obtained by comparison. In sequential scanning the error signal is obtained by comparing the strength of echo returns from successive pulses. In monopulse systems the pulse is divided into four separate parts in the waveguide system. The four parts are radiated by separate feed horns, and are combined by the antenna into a single beam. Return echoes are divided back into four parts. The relative strength of the parts are compared to obtain target position with respect to the antenna axis (fig. 15-9).

The heart of this monopulse system is called the microwave comparator. It consists of four feed horns, four hybrid rings, and connecting waveguide sections.

NOTE: Prior to the discussion of monopulse comparator operation, a review of the basic operation of a hybrid ring is considered necessary. This discussion follows.

HYBRID RING REVIEW

The hybrid ring is used principally as a duplexer in a high power radar system. However, a combination of three hybrid rings may be used as a balance mixer. This type of mixer is very effective in isolating the receiver from the transmitter during the time the transmitter is firing.

A simplified version of the hybrid ring used as a duplexer is illustrated in figure 15-10 (A) and (B). The operation during transmission and reception is illustrated in parts (C) and (D), respectively.

During TRANSMISSION (fig. 15-10 (C)), the operation of the hybrid ring may be explained as follows:

1. The field from the transmitter enters arm 3. At the junction with the ring, the field divides into two out-of-phase fields, one moving clockwise around the ring and the other, counterclockwise. (See fig. 15-11 (B) (1)). In order that energy may be coupled to the antenna via arm 1, the E fields arriving at the arm 1 junction must be 180° out of phase (fig. 15-11 (B) (3)).

2. The field moving clockwise around the ring from arm 3 fires the TR tube in arm 4, and the energy is blocked from the receiver or load. A high impedance (equivalent to an open circuit) appears at the junction of arm 4 and the ring. There is a phase reversal at this junction (fig. 15-11 (B) (4)).

Figure 15-9.—Amplitude changes of received energy with target position.

1069101

their name and the date and time the watch is being performed. Examples of entries made in such a log are crash phone check, time checks, intercommunications checks, and any other data pertinent to operations that transpires during the watch.

PASS DOWN THE LINE (PDL) LOG

This type of log may be maintained for the purpose of passing instructions from crew to crew and to insure that night crews have access to information etc. put out by supervisors who work straight days. Also it may be used to relay local verbal standing or temporary orders issued by the division or operations officer. It is generally an informal type log strictly for the purpose of getting the word to everyone.

RADAR FACILITIES RECORDS

Radar facilities must keep an accurate record of all radar approaches and services provided. The most common method, in addition to approach control flight progress strips where applicable, is a daily run sheet. Various formats are used; however, the information recorded includes the aircraft involved, frequency used, weather, type of approach or service provided, and the controller. All this information, along with information from other positions, is the basis for the monthly and quarterly reports required of such facilities. Care must be taken to insure that complete information is recorded to provide for accurate reports.

FLIGHT DATA AND STATUS BOARDS

To reduce the constant answering in the air operations office of questions from the general public, flight data and status boards are useful tools to the Air Controlman. The actual size, shape, and construction, as well as the manner in which the information is portrayed, undoubtedly may vary from station to station. However, the information normally displayed on the flight data board for inbound flights is as follows:

1. Bureau number.
2. Type aircraft
3. Point of departure.
4. ETA.
5. Pertinent remarks.

Status boards are usually of the type to show the present status of the various navigational aids at the particular station. It is also possible that an additional status board may be maintained by the Air Controlman at stations assigned aircraft for search and rescue purposes. This type status board normally contains information as to the flight status of the aircraft assigned and pertinent information concerning the crew.

Status boards may be maintained in a RATCC showing the area of responsibility and adjoining airspace, airways and jet routes, SID's, fixes, handoff points, holding points and holding pattern airspace areas, and the published approaches available for reference at operating positions.

When assigned the duty of maintaining any status board, remember that the information is important and should be kept neat, accurate, and current at all times.

10718

APPENDIX 1

DEFINITIONS AND ABBREVIATIONS

ACIC.—Aeronautical Charting and Information Center.

ADVISORY SERVICE.—Advice and information provided by a facility to assist pilots in the safe conduct of flight and aircraft movement.

AIM.—Airman's Information Manual.

AIR COORDINATING COMMITTEE (ACC).—A committee organized to investigate aviation problems and developments affecting more than one government agency.

AIRCRAFT MOVEMENT INFORMATION SECTION (AMIS).—A service to provide aircraft identification for security purposes.

AIRCRAFT OPERATIONS.—Arrivals or departures of aircraft at airports.

AIR DEFENSE COMMAND (ADC).—A service providing for national defense.

AIR DEFENSE IDENTIFICATION ZONE (ADIZ). —Area within which the security control of air traffic is exercised.

AIR-GROUND COMMUNICATIONS.—Air-to-ground and ground-to-air communication; used in traffic control, search and rescue, inflight advisory service, emergency recall, security identification, and air safety advice.

AIRMET.—Airmen's Meteorological Information.

AIRPORT.—An area of land or water that is used or intended to be used for the landing and takeoff of aircraft, and includes its buildings and facilities, if any.

AIRPORT SURFACE DETECTION EQUIPMENT (ASDE).—A short distance radar used for the control of aircraft and surface vehicles on an airport.

AIRPORT SURVEILLANCE RADAR (ASR).—A relatively short range radar used by control tower personnel for arrival and departure control within a 30-mile area.

AIRPORT TRAFFIC AREA.—Unless otherwise specifically designated, that airspace within a horizontal radius of 5 statute miles from the geographical center of any airport at which a control tower is operating, extending from the surface up to, but not including, 2,000 feet above the surface.

AIRPORT TRAFFIC CONTROL SERVICE.—Air traffic control service provided by an airport traffic control tower for aircraft operating on the movement area and in the vicinity of an airport.

AIRPORT TRAFFIC CONTROL TOWER (TOWER).—A facility providing airport traffic control service.

AIR ROUTE TRAFFIC CONTROL CENTER (CENTER).—A facility established to provide traffic control service to instrument flight rules (IFR) flights operating within controlled airspace and principally during the en route phase of flights.

AIR TRAFFIC.—Aircraft in operation anywhere in the airspace and on that area of an airport normally used for the movement of aircraft.

AIR TRAFFIC CLEARANCE.—Authorization by air traffic control facilities, for the purpose of preventing collision between known aircraft, for an aircraft to proceed under specified traffic conditions within controlled airspace.

AIR TRAFFIC CONTROL FACILITY (FACILITY).—A facility providing air traffic control service.

AIR TRAFFIC CONTROL SERVICE (CONTROL). —A service provided for the purpose of promoting the safe, orderly, and expeditious flow of air traffic including airport, approach, and en route air traffic control services.

AIR TRAFFIC CONTROL SPECIALIST (CONTROLLER).—A duly authorized person providing air traffic control service.

ALERT AREA.—Airspace within which flights are not restricted but pilots should be aware that a high volume of unusual aerial activity exists.

ALNOT.—Alert notice.

10719

ALTERNATE AIRPORT.—An airport, specified in the flight plan, to which a flight may proceed when a landing at the point of first intended landing becomes inadvisable.

ALTIMETER.—An aneroid barometer graduated to show height instead of pressure.

ALTIMETER SETTING.—A barometric pressure in inches for setting a pressure scale type altimeter.

ALTIMETER SETTING INDICATOR.—A direct reading aneroid barometer graduated to show station pressure corrected to sea level.

ALTRV.—Altitude reservation.

AMOS.—Automatic Meteorological Observing System.

ANEROID BAROMETER.—An instrument for measuring atmospheric pressure.

APPROACH CONTROL FACILITY.—A facility providing approach control service.

APPROACH CONTROL SERVICE.—Air traffic control service, provided by a terminal area traffic control facility, for arriving and departing IFR aircraft and, on occasion, VFR aircraft.

APPROACH FIX.—The fix from or over which final approach (IFR) to an airport is executed.

APPROACH GATE.—That point on the final approach course which is 1 mile from the approach fix on the side away from the airport or 5 miles from the landing threshold, whichever is farther from the landing threshold.

APPROACH LIGHTING.—A configuration of ground lights placed in the approach area to a runway, to assist the pilot in making an approach to that runway.

APPROACH SEQUENCE.—The order in which aircraft are positioned while awaiting approach clearance or while on approach.

ARAC.—Army radar approach control facility.

ARC.—The track over the ground of an aircraft flying at a constant distance from a navaid by reference to distance measuring equipment (DME).

ARCP.—Air refueling control point.

ARIP.—Air refueling initial point.

ARRIVAL.—An aircraft arriving at an airport.

ATC.—Air Traffic Control.

ATCRBS.—Air traffic control radar beacon system.

ATIS.—Automatic Terminal Information Service.

AUTOMATIC DIRECTION FINDER (ADF).—An L/MF device, giving relative bearings on the L/MF navaids. The ADF is normally used for homing purposes but can be used in conjunction with the magnetic compass to provide line-of-position information.

AVIATION WEATHER OBSERVATION.—An evaluation made from the surface, according to set procedures, of those weather elements which are most important for aircraft operations.

AZ-EL.—A type of radarscope that provides azimuth, range and elevation data. This unit of radar is used by precision radar units.

AZIMUTH.—Angular position or bearing in a horizontal plane.

BASE LINE.—The line formed by the sweep on a cathode-ray tube. Commonly referred to as time base.

BASIC VFR.—Ceiling of 1,000 feet and visibility of 3 miles.

BEARING.—The direction of the line of sight, from the radar antenna to the target, measured in degrees.

BEARING CURSOR.—A mechanical bearing line for reading target and/or course. Also commonly known as navigation head.

BLIND ZONE.—The area within the coverage of the radar reception pattern where radar echoes cannot be received.

CALIBRATION MARKERS.—Indications on the screen of a radar indicator which divide the range scale into known intervals for range determination, or for checking against mechanical indicating dials, scales, or counters.

CANADIAN AIR DEFENSE IDENTIFICATION ZONE (CADIZ).—An ADIZ located in Canada.

CARDINAL ALTITUDES OR FLIGHT LEVELS.—Odd or even 1,000-foot altitudes or flight levels. Examples: 5,000, 6,000, 7,000, FL 250, FL 260, FL 270.

CEILING.—The height above the ground or water of the lowest layer of clouds or obscuration phenomena that is reported as "broken," "overcast," or "obscuration," and not classified as "thin," or "partial."

CENTER's AREA.—The specified airspace within which an air route traffic control center provides air traffic control and advisory service.

CENTRAL ALTITUDE RESERVATION FACILITY (CARF).—A facility established to act as a clearing house for mission type flights.

10720

CLEARANCE.—An air traffic control clearance.

CLEARANCE LIMIT.—The fix to which an aircraft is issued an air traffic clearance.

CHECK OBSERVATION.—An abbreviated surface aviation weather observation taken to determine if certain elements have changed by some specific value since the preceding aviation observation.

CODES.—The numbers assigned to the multiple pulse reply signals transmitted by ATCRBS and SIF transponders.

COMBINED STATION/TOWER (CS/T).—A facility resulting from the combining of a Flight Service Station and an Airport Traffic Control Tower, as is done for economy at relatively low activity airports.

COMMON SYSTEM.—Common civil/military system of air traffic control and navigation.

COMPASS LOCATOR.—An L/MF nondirectional radio beacon installed in the approach area, at or near the ILS outer marker and/or middle marker, to be used with an airborne direction finder in making an approach to landing.

CONAC.—Continental Air Command.

CONTACT APPROACH.—An approach wherein an aircraft on an IFR flight plan, operating clear of clouds with at least 1 mile flight visibility and having received an air traffic control authorization, may deviate from the prescribed instrument approach procedure and proceed to the airport of destination by visual reference to the surface.

CONTROLLED AIRSPACE.—Airspace designated as continental control area, control area, control zone, or transition area, within which some or all traffic may be subject to air traffic control.

(1.) CONTINENTAL CONTROL AREA.—airspace within the continental United States at and above 14,500 feet MSL, excluding the State of Alaska, airspace less than 1,500 feet above terrain, and prohibited and restricted areas (except certain specified restricted areas).

(2.) CONTROL AREA.—Unless otherwise provided, airspace extending upward from 700 feet above the surface (until designated from 1,200 feet above the surface or from at least 300 feet below the MEA, whichever is higher) to the base of the continental control area.

(3.) CONTROL ZONE.—Airspace extending upward from the surface of the earth which may include one or more airports and is normally a circular area of 5 statute miles in radius with extensions where necessary to include instrument approach and departure paths.

(4.) TRANSITION AREA.—Airspace extending upward from 700 feet or more above the surface of the earth when designated in conjunction with an airport for which an approved instrument approach procedure has been prescribed, or from 1,200 feet or more above the surface of the earth when designated in conjunction with airway route structures or segments. Unless otherwise limited, transition areas terminate at the base of the overlying controlled airspace.

CONTROL SLASH.—That slash, of a beacon target consisting of more than one slash, which represents the actual position of the associated aircraft. The control slash is always the one closest to the interrogating radar beacon site.

CORNER REFLECTOR.—A metal device of triangular shape, used for the purpose of providing a strong radar echo from a known position on the ground.

CPN.—"C" for air transportable, "P" for pulse radar, "N" for navigation aid. This is a self-contained truck-trailer unit with both surveillance and precision equipment (military).

CPS.—Air transportable/pulse radar/"S" for search radar. Equipment used for long range early warning purposes (military).

CRUISE.—A word used instead of the word "maintain" in an ATC clearance to indicate to a pilot that climb to and descent from the assigned altitude may be made at his discretion.

CRUISING ALTITUDE.—A level determined by vertical measurement from mean sea level.

DECODER.—The device used to deciper signals received from ATCRBS and SIF transponders to effect their display as select codes.

DIRECTION FINDER (DF).—VHF/UHF navigation aid operated by personnel on the ground to furnish azimuth information to aircraft.

DISTANCE MEASURING EQUIPMENT (DME).—Equipment (airborne and ground) used to measure, in nautical miles, the distance of an aircraft from a navigational aid.

DME FIX.—A geographical position determined by reference to a navigational aid which provides distance and azimuth information and defined by a specified distance in nautical miles and a radial in degrees magnetic from the aid.

DME SEPARATION.—Spacing of aircraft in terms of distances determined by reference to distance measuring equipment (DME).

ECHO.—The signal reflected by a target (fixed or moving) to a radar receiver. Also, the deflection or indication, on the screen of a cathode-ray tube, representing a target.

EDDY.—A local irregularity in a wind. All winds near the earth's surface contain eddies, which at any given place produce gusts or lulls. Air containing numerous eddies is said to be turbulent.

EN ROUTE AIR TRAFFIC CONTROL SERVICE.—Air traffic control service provided aircraft on an IFR flight plan, generally by centers, when these aircraft are operating between departure and destination terminal areas.

ESTABLISHED AIRWAYS/ROUTES.—Preplanned and/or published airways or routes not requiring "on-the-spot" computation by the controller to determine airspace to be protected. These include:

(1.) A designated airway, published in the FAR's, plus any locally charted turning-radius airspace.

(2.) A designated route, published in the FAR's and its locally charted, associated, protected airspace, plus any turning-radius airspace.

(3.) A direct route, locally charted by a facility for sector use but not disseminated in the FAR's, and its associated, protected airspace plus any turning-radius airspace.

ESTIMATED TIME OF ARRIVAL (ETA).—Estimated time of arrival over the point of first intended landing.

EXPECTED APPROACH CLEARANCE TIME (EAC).—The time at which it is expected that an arriving aircraft will be cleared to commence approach for a landing.

EXPECTED FURTHER CLEARANCE TIME (EFC).—The time at which it is expected that additional clearance will be issued to a flight.

FACILITY.—See air traffic control facility.

FANMARKER (FM).—A radio navigation aid creating a pattern in the vertical plane, placed perpendicularly across an airway to mark certain points along the airway course.

FAR.—Federal Aviation Regulations.

FAST TIME CONSTANT (FTC).—An anticlutter circuit, effective in breaking up large blocks of signals into small echoes so that aircraft might be tracked more easily.

FAWS.—Flight Advisory Weather Service.

FEDERAL AVIATION ADMINISTRATION (FAA).—The administration of the United States created to provide for the regulation and promotion of civil aviation in such a manner as to best foster its development and safety, and to provide for the safe and efficient use of the airspace by both civil and military aircraft.

FINAL APPROACH-IFR.—The flightpath of an aircraft which is inbound to the airport on an approved final instrument approach course, beginning at the point of interception of that course and extending to the airport or the point where circling for landing or missed approach is executed.

FINAL APPROACH-VFR.—A flightpath of a landing aircraft in the direction of landing along the extended runway centerline from the base leg to the runway.

FINAL CONTROLLER.—That controller providing final approach guidance utilizing precision approach radar equipment.

FIX.—A geographical position determined by visual reference to the surface, by reference to one or more radio navaids, by celestial plotting, or by another navigational device.

FLIGHT LEVEL (FL).—A level of constant atmospheric pressure related to a reference datum of 29.92 inches in mercury. Each is stated in 3 digits that represent hundreds of feet. For example, FL 250 represents a barometric altimeter indication of 25,000 feet. FL 255 indicates 25,500 feet.

FLIGHT PLAN.—Specified information relating to the intended flight of an aircraft that is filed orally or in writing with an air traffic control facility.

FLIGHT SERVICE STATION (FSS)—An FAA Communication Station.

FLIGHT SERVICE SPECIALIST.—Flight Service Station personnel.

10722

FLIGHT VISIBILITY.—The average forward horizontal distance from the cockpit of an aircraft in flight at which prominent unlighted objects may be seen and identified by day and prominent lighted objects may be seen and identified by night.

FLOW CONTROL.—Limitations applied to the flow of traffic to keep elements of the system, such as airports or airways, from becoming overloaded.

FOG.—A cloud at the earth's surface.

FPN.—Fixed pulse radar navigational aid. Precision equipment or AZ-EL scope.

FPS.—Fixed pulse radar search equipment (military).

GAIN.—Control for increasing or decreasing the amplification of the radar data on the scope.

GENERAL AVIATION.—That segment of aviation operating for private purposes, either for individual pleasure or transportation of business personnel, crop dusting, etc.

GLAZE.—Term applied by the U.S. Weather Bureau to a smooth coating of ice on terestrial objects due to the freezing of rain.

GRASS.—A voltage fluctuation or electronic noise introduced into the receiver in such a manner that it appears on the scope. Sometimes referred to as snow. It gives the scope a speckled appearance so that weak signals might not be observed.

GROUND CLUTTERS.—Radar echoes reflected from ground targets or objects. In poor radar locations, obscurement of relatively large areas of the radar indicator may result.

GROUND CONTROLLED APPROACH (GCA).—The radar system developed to give azimuth, range, and elevation along a fixed approach path.

GROUND CONTROLLED INTERCEPT (GCI).—Long range high altitude equipment used by military AC & W units.

GROUND VISIBILITY.—Prevailing horizontal visibility near the earth's surface as reported by the U.S. Weather Bureau or an accredited observer.

GUST.—A sudden, intermittent increase in windspeed, with at least 9 knots variation between peaks and lulls.

HAIL.—A form of precipitation consisting of balls or irregular lumps of ice, often of considerable size, having a complex structure.

HAZE.—A lack of transparency in the atmosphere caused by the presence of dust or of salt particles left by evaporated ocean spray.

H FACILITY.—An L/MF nondirectional radio beacon primarily intended for use with airborne direction finders to give bearing information to the pilot.

HF COMMUNICATIONS.—Communications using highradio-frequencies (HF).

HH FACILITY.—A high powered H facility, used primarily for transoceanic or other long distance flights.

HIGH PRESSURE SYSTEM.—An area of high barometric pressure; an anticyclone.

HIGH RADIOFREQUENCY (HF).—3,000 to 30,000 kilohertz.

HOLDING.—A predetermined maneuver which keeps an aircraft within a specific airspace while awaiting further clearance.

HOLDING FIX.—A specified fix used as a reference point in establishing and maintaining the position of an aircraft while holding.

ICAO.—International Civil Aviation Organization.

IDENT FEATURE.—The special feature in ATCRBS equipment and the I/P feature in certain SIF equipment used to distinguish one displayed select code from other codes.

IFR AIRCRAFT.—An aircraft conducting flight in accordance with Instrument Flight Rules.

IFR CONDITIONS.—Weather conditions below the minimum for flight under Visual Flight Rules.

INSTRUMENT APPROACHES.—Approaches to airports made by aircraft under instrument flight rules.

INSTRUMENT FLIGHT RULES (IFR).—Rules prescribed by Federal Aviation Regulations governing instrument flight.

INSTRUMENT LANDING SYSTEM (ILS).—Consists of four radio transmitting stations on the ground and in the vicinity of an airport radiating directional signals to approaching aircraft. The received signals operate indicators in the aircraft to alert the pilot of any deviation from the ideal safe approach path to the correct touchdown point on the runway.

INTERFERENCE.—Confusing signals or patterns produced on a radar indicator by another radar on the same frequency, and more rarely, by the effects of nearby electrical apparatus or machinery, or by atmospheric phenomena.

10723

INTERNATIONAL FLIGHT SERVICE STATION (IFSS).—An FAA Communication Facility which provides services for overseas and international aircraft operations.

INTERPHONE.—See Service F.

INTERROGATOR.—The ground-based surveillance radar beacon transmitter-receiver which scans in synchronism with a primary radar, transmitting discrete radio signals which repetitiously request all transponders, on the mode being used, to reply. The replies received are then mixed with the primary radar video to be displayed on the same plan position indicators.

I/P FEATURE.—See IDENT feature.

ISJTA.—Intensive student jet training area.

ITINERANT TRAFFIC.—Air traffic moving from one locality to another, as opposed to local traffic.

JET ADVISORY SERVICE.—The service provided certain civil aircraft while operating within radar and nonradar jet advisory areas. Within radar jet advisory areas, civil aircraft receiving this service are provided radar flight following, radar traffic information, and vectors around observed traffic. In nonradar jet advisory areas, civil aircraft receiving this service are afforded standard IFR separation from all other aircraft known to ATC to be operating within these areas.

JET ROUTES.—Routes at and above 18,000 feet.

JET STREAM.—A concentrated core of high speed winds embedded in the general flow.

LANDING THRESHOLD.—The beginning of that portion of a runway usable for landing.

LATERAL SEPARATION.—The lateral spacing of aircraft at the same altitude by requiring operation on different routes or in different geographical locations.

LINE OF POSITION.—A navigational term meaning the line of position along the earth's surface defined by some characteristic of a navigational aid or technique.

LOCAL OBSERVATION.—An abbreviated weather observation taken at specified intervals, usually every 15 minutes, when aircraft operations are impending and when weather conditions are below certain operational weather limits; also taken when an aircraft accident is reported in the vicinity.

LOCAL TRAFFIC.—Aircraft operating in the traffic pattern of the landing area concerned.

LONGITUDINAL SEPARATION.—The longitudinal spacing of aircraft at the same altitude by a minimum distance so that after one aircraft passes over a specified position, the next aircraft at the same altitude will not arrive over the same position within less than the standard minimum separation.

MAP OVERLAY.—Plexiglas sheet laid over the face of the scope, etched to display radio facilities and landmarks of the area under radar coverage.

MARKER.—Electronic range or bearing indication on a radar indicator.

MARSA.—Military assumes responsibility for separation of aircraft.

MICROSECOND.—One-millionth of a second. The unit of time commonly used in radar.

MICROWAVE EARLY WARNING (MEW).—This is the long range-high altitude equipment used for coastal monitoring units (military).

MIDDLE MARKER.—Radio beacon emitting a vertical fanshaped pattern, normally placed 3,500 feet out from the approach end of the runway, along the localizer course.

MILLIBAR.—A unit of pressure equal to a force of 1,000 dynes per square centimeter.

MINIMUM CROSSING ALTITUDE (MCA).—The lowest altitude at certain radio fixes at which an aircraft must cross when proceding in the direction of a higher minimum en route IFR altitude.

MINIMUM EN ROUTE IFR ALTIUDE (MEA). —The altitude in effect between radio fixes which assures acceptable navigational signal coverage and meets obstruction clearance requirements between those fixes.

MINIMUM OBSTRUCTION CLEARANCE ALTITUDE (MOCA).—The specified altitude in effect between radio fixes on VOR airways, off-airway routes, or route segments which meets obstruction clearance requirements for the entire route segment and which assures acceptable navigational signal coverage only within 22 miles of a VOR.

MINIMUM RECEPTION ALTITUDE (MRA).—The lowest altitude required to receive adequate signals to determine specific VOR/VORTAC/TACAN fixes.

MODE.—The number or letter referring to the specific pulse spacing of the signals transmitted by an interrogator.

MOVEMENT AREA.—The part of an airport reserved for the taking off, landing, and taxiing of aircraft.

10724

MOVING TARGET INDICATOR (MTI).—A device which limits the display of radar information primarily to that of moving objects; e.g., aircraft or surface vehicles.

MSL.—Mean sea level.

NATIONAL AIRSPACE SYSTEM.—The common system of air traffic and air traffic control encompassing communication facilities, air navigation facilities, airways, controlled airspace, special use airspace, and flight procedures authorized by Federal Air Regulations for domestic and international aviation.

NAVAID.—Navigational aid.

NOTAM.—A Notice to Airmen in message form requiring expeditious and wide dissemination by telecommunications.

NATIONAL SEARCH AND RESCUE PLAN.—An interagency agreement whose purpose is to provide for the effective utilization of all available facilities in all types of search and rescue missions.

OUTER FIX.—A fix in the destination terminal area, other than the approach fix, to which aircraft are normally cleared by an air route traffic control center or a terminal area traffic control facility, and from which aircraft are cleared to the approach fix or final approach course.

OUTER MARKER.—Radio beacon emitting a vertical fanshaped pattern, normally placed 4 1/2 miles out from the approach end of the runway, along the localizer course.

PARALLAX.—The apparent displacement of a target due to the eye position of the observer. Occurs when a map overlay system is used.

PENETRATION.—That portion of a published high altitude instrument approach procedure which prescribes a descent path from the fix on which the procedure is based to a fix or altitude from which an approach to the airport is made.

POSITIVE CONTROL AREA.—Airspace so designated by FAR 71.193 and depicted on high altitude charts between FL 180 or FL 240 up to and including FL 600.

PRECAUTIONARY APPROACH.—A procedure designed to afford a pilot experiencing flight difficulties a means of landing safely and expeditiously while providing a safe ejection altitude if he elects to discontinue the approach.

PRECIPITATION.—A collective name for deposits of atmospheric moisture in liquid and solid form, including rain, snow, hail, dew, hoar frost, etc.

PRECISION APPROACH.—An instrument approach conducted in accordance with directions issued by a controller referring to the surveillance radar display until the aircraft is turned onto final approach and, thereafter, to a precision approach radar display.

PRECISION APPROACH RADAR (PAR).—Utilizing the AZ-EL scopes, it gives the controller three types of radar data—azimuth, elevation, and range. Used for the final approach portion of the approach.

PRESENTATION.—The form which the radar echo signals are made to take on the cathode-ray tube screen, as determined by the nature of the sweep circuit utilized. Examples: AZ-EL or surveillance presentation.

PREVAILING VISIBILITY.—The greatest horizontal visibility which is equalled or exceeded through half of the horizon circle. It need not be a continuous half. In the case of rapidly varying conditions, it is the average of the prevailing visibility while the observation is being taken.

PRIMARY RADAR.—See radar.

PROHIBITED AREA.—Airspace identified by an area on the surface of the earth within which the flight of aircraft is prohibited. A prohibited area may be established by the President of the United States or any State of the United States.

PULSE.—A momentary, sharp change in a current or voltage, followed almost immediately thereafter by a sharp return to normal.

PULSE LENGTH OR DURATION.—Elapsed time, from start to finish, of a single pulse. Radar uses one antenna for both transmitting and receiving. Transmissions must cease prior to the moment of reception. A system of pulsed energy makes the use of one antenna possible. The length of time the transmitter is ON during one cycle is determined by the pulse length.

PULSE REPETITION FREQUENCY (PRF).—After a pulse is fired, the transmit-receive switch shifts to receive. The transmitter remains off for a period greater than the time required for the pulse to return. This process is repeated continuously at a rate known as the pulse repetition frequency.

10725

RADAR (RADIO DETECTION AND RANGING).—A device which, by measuring the time interval between transmission and reception of radio pulses and correlating the angular orientation of the radiated antenna beam or beams in azimuth and/or elevation, provides information on range, azimuth, and/or elevation of objects in the path of the transmitted pulses.

(1.) PRIMARY RADAR.—A radar system in which a minute portion of a radio pulse transmitted from a site is reflected off an object and then received back at that site.

(2.) RADAR BEACON (SECONDARY RADAR).—A radar system in which the object to be detected is fitted with cooperative equipment in the form of a radio receiver/transmitter (transponder). Radio pulses transmitted from the searching transmitter/receiver (interrogator) site are received in the cooperative equipment and used to trigger a distinctive transmission from the transponder. This latter transmission, rather than a reflected signal, is then received back of the transmitter/receiver site.

RADAR ADVISORY.—The term used to indicate that the provision of advice and information is based on radar observation. (See advisory service.)

RADAR CONTACT.—The term an air traffic controller uses to inform an aircraft that it is identified on the radar display, that radar service can be provided until radar identification is lost or radar service is terminated, and that when the aircraft is informed of "radar contact" it automatically discontinues reporting over compulsory reporting points.

RADAR FLIGHT FOLLOWING.—The radar tracking of identified aircraft targets and the observation of the progress of these flights sufficiently to retain identity.

RADAR HANDOFF.—That action whereby radar identification of, radio communication with and, unless otherwise specified, control responsibility for an aircraft is transferred from one controller to another without interruption of radar flight following.

RADAR IDENTIFICATION.—The process of ascertaining that a radar target is the radar return from a particular aircraft.

RADAR INDICATOR.—A unit of radar equipment which provides a visual indication of the reflected energy received, using a cathode-ray tube or tubes for such indication. The radar indicator comprises, besides the cathode-ray tube, the sweep and calibration circuit, and associated power supplies.

RADAR RECEIVER.—An instrument which amplifies radio frequency signals, demodulates the RF carrier, further amplifies the desired signal and delivers it to the indicator. It differs from the usual radio receiver in that it is more sensitive, has a better signal to noise ratio, and is designed to pass a pulse type signal.

RADAR SERVICE.—A term which encompasses one or more of the following services based on the use of radar which can be provided by a controller to a radar-identified aircraft. These include:

(1.) Radar separation—radar spacing of aircraft in accordance with established minimums.

(2.) Radar navigational guidance—vectoring aircraft to provide course guidance.

(3.) Radar monitoring—the radar flight-following of an aircraft whose primary navigation is being performed by its pilots to observe and note deviations from its authorized flight path, airway, or route. This includes noting the aircraft's position relative to approach fixes.

RADAR SURVEILLANCE.—The radar observation of a given geographical area for the purpose of performing some radar function.

RADAR TRACKING.—The observation of the movement of specific radar targets.

RADAR TRANSMITTER.—A unit of radar equipment in which the radiofrequency power is generated and pulse modulated. Differs from communications transmitter in frequency and type of modulation used.

RADIAL.—A magnetic bearing extending from a VOR/VORTAC/TACAN.

RANGE MARKS.—Electronic reference lines appearing on the scope to indicate distance from either touchdown or the antenna site.

RANGE SELECTOR.—On surveillance equipment the controller has a choice of ranges to be presented. Usually four or five different setting from 5 miles to over 30 miles.

10726

RAPCON.—A radar approach control facility established by or in cooperation with the U.S. Air Force primarily to serve air traffic at an Air Force base.

RATCC.—A radar air traffic control center established by or in cooperation with the U.S. Navy primarily to serve air traffic at a naval air station.

RCC.—Search and rescue coordination center.

RCR.—Runway conditions reading.

RECEIVING CONTROLLER/FACILITY.—A controller/facility receiving control of an aircraft from another controller/facility.

RECORD OBSERVATION.—A type of aviation weather observation taken at scheduled intervals unless otherwise specified; the most complete of all such observations.

REPORTING POINT.—A geographical location in relation to which the pilot of an aircraft reports his position to air traffic control.

RESOLUTION:

(1). Range—The mimimum range difference between two separate targets at the same bearing that will allow both to appear as distinct, separate echoes on the indicator.

(2.) Bearing—The minimum angular separation between two targets at the same range that will allow both to appear as distinct, separate echoes on the indicator.

(3.) Elevation—The minimum angular separation in a vertical plane between two targets at the same range and bearing that will allow both to appear as distinct, separate echoes on the indicator.

RESTRICTED AREA.—An area in which there is a hazard, generally invisible, to flight or navigation such as aerial gunnery, guided missile, artillery, or other type firing. Permission must be granted to a flight before it may traverse an area during those periods when it is live, or in use.

RIME.—A rough or feathery coating of ice.

ROUTE.—A defined path, consisting of one or more courses, which an aircraft traverses in a horizontal plane over the surface of the earth.

RUNWAY END.—The end of that portion of a runway useable for landing or takeoff.

RUNWAY VISUAL RANGE (RVR).—The maximum distance in the direction of takeoff or landing at which the runway, or specified lights or markings delineating it, can be seen from a position above a specified point on its centerline, at a height corresponding to the average eye-level of pilots at touchdown.

SAR.—Search and rescue.

SCAN.—That area in space covered by the radar antenna pattern. It may be an area of 360° with varying ranges as on the airport surveillance radar, or a restricted area such as that of the precision radar.

SCOPE.—The face of the cathode-ray tube that is visible to the operator on which appears a display of a given area of coverage. It contains the visual display of the reception of the radar system and video mapping.

SCOPE ALINEMENT.—A means of checking the accuracy of the radar data received and displayed. It also is the means of making minor corrections to the radar display or attain proper and correct positioning of radar data.

SEARCH AND RESCUE FACILITY.—A facility responsible for maintaining and operating a search and rescue service for occupants of missing or downed aircraft.

SECONDARY RADAR.—(See radar.)

SELECT CODE.—That code displayed when the ground interrogator and the airborne transponder are operating on the same mode and code simultaneously.

SELS.—Severe Local Storms.

SENSITIVITY TIME CONTROL (STC).—This is an automatic electronic aid that reduces the gain of targets close in and increases the gain on targets at distance ranges.

SEPARATION.—Spacing of aircraft to achieve their safe and orderly movement in flight and while landing and taking off.

SEPARATION MINIMUMS.—The minimum longitudinal, lateral, or vertical distances by which aircraft are spaced through the application of air traffic control procedures.

SERVICE A.—A teletypewriter network used to collect and distribute national service weather reports and NOTAM's.

SERVICE B.—A teletypewriter network used to distribute all messages pertaining to VFR flights and to supplement Service F for certain types of IFR movement and control messages.

SERVICE C.—A teletypewriter network used to collect and disseminate 3- and 6-hourly weather data, including upper air observations and weather map data, terminal and regional forecasts and weather advisories.

SERVICE F.—A system of telephone circuits (interphone) which are exclusive and

10727

Figure 15-10.—Hybrid ring duplexer showing E lines during transmission and reception.

3. The field moving counterclockwise from arm 3 "sees" a short circuit at the arm 2 junction when the TR tube in arm 2 fires, and there is no phase reversal at this junction. The amount of energy entering waveguide 2 is limited by the action of the spark gap (not shown in the figure).

4. If the complete circuits are traced out (fig. 15-10 (C)), it will be seen that the clockwise and counterclockwise signals arriving at the junction of arm 1 are of opposite polarity and will be propagated through the arm to the antenna (fig. 15-11 (B) (3)).

During RECEPTION (fig. 15-10 (D)), the operation of the hybrid ring may be explained as follows:

1. The relatively weak signal from the antenna enters arm 1 and divides at the junction into two out-of-phase components (fig. 15-11 (B) (1)). To avoid coupling energy into the

1076301

continually available for direct communications between ground stations for air traffic control purposes, to handle messages of aircraft position reports, clearance and requests for clearance for civil aircraft to enter or proceed through controlled airspace in accordance with instrument flight rules.

SERVICE O.—A teletypewriter system used to exchange meteorological data with locations outside the continental United States. Also used to disseminate meteorological information from overseas sources to key terminals and forecast centers within the United States.

SERVO.—An electromechanical system which is used for moving antenna(s) and giving an indication of their position.

SFA.—Single frequency approach.

SID.—Standard instrument departure.

SIF.—Selective identification feature (of the basis Mark X radar beacon system).

SIGMET.—Significant Meteorological Information.

SINGLE-PILOTED AIRCRAFT.—An aircraft possessing one set of flight controls, tandem cockpits, or two sets of flight controls but operated by one pilot.

SLANT RANGE.—The straight line distance to the target. Radar range is determined by slant line range and not the normal geographic ranging.

SLASH.—A radar beacon reply displayed as an elongated target.

SPECIAL OBSERVATION.—A category of aviation weather observation taken to report significant changes in one or more of the observed elements since the last preceeding record, record-special, or special observation.

SPECIAL VFR CONDITIONS (SPECIAL VFR MINIMUM WEATHER CONDITIONS.)—Weather conditions which are less than basic VFR weather conditions and which permit flight under Visual Flight Rules.

SPECIAL VFR OPERATIONS.—Aircraft operating in accordance with clearances within control zones in weather conditions less than the basic VFR weather minimums.

SQUALL.—A wind that increases suddenly in speed, maintains a peak speed of 16 knots or more over a period of 2 or more minutes, and then decreases in speed.

STATIONARY RESERVATIONS.—Altitude reservations which encompass activities in a fixed area. Stationary reservations may include such as special test of weapons systems or equipments, certain U.S. Navy carrier, fleet, and antisubmarine operations, rocket, missile and drone operations, and certain aerial refueling or similar operations.

STRAIGHT-IN APPROACH—IFR.—An instrument approach wherein final approach is begun without first having executed procedure turn.

STRAIGHT-IN APPROACH—VFR.—Entry of the traffic pattern by interception of the extended runway centerline without executing any other portion of the traffic pattern.

SUNSET AND SUNRISE.—The mean solar times of sunset and sunrise as published in the Nautical Almanac, converted to local standard time for the locality concerned. Within Alaska, the end of evening civil twilight and the beginning of morning civil twilight, as defined for each locality.

SURVEILLANCE APPROACH.—An instrument approach conducted in accordance with directions issued by a controller referring to the surveillance radar display.

SWEEP.—A luminescent line formed by a stream of electrons on the face of the radarscope.

TACAN.—UHF navigational aid (omnidirectional course information).

TACAN-ONLY AIRCRAFT.—An aircraft possessing TACAN but no VOR navigational system capability.

TAKEOFF CLEARANCE.—Authorization by an airport traffic control tower for an aircraft to take off.

TAKEOFF THRESHOLD.—The beginning of that portion of a runway usable for takeoff.

TARGET.—The indication shown on a radar display resulting from a primary radar return or a radar beacon reply.

TELETYPEWRITER SYSTEM.—A system of circuits, either landline or radio, whereby messages are transmitted or received in typewritten form.

TERMINAL AREA FACILITY.—A facility (RAPCON, RATCC or tower) providing air traffic control service for arriving and departing IFR aircraft and, on occasion, tower en route control service.

THUNDERSTORM.—A local storm produced by a cumulonimbus cloud, and always accompanied by lightning and thunder. It is usually accompanied by strong gusts of wind, heavy rain, and sometimes hail. It is usually of short duration, seldom over two hours.

CS701 10728

TOWER EN ROUTE CONTROL SERVICE.—Departure, en route and arrival control service provided to IFR aircraft by one or more terminal area facilities.

TRACK.—The flightpath of an aircraft over the surface of the earth.

TRACON.—Terminal Radar Control Facility.

TRAFFIC INFORMATION—RADAR.—Information issued to alert an aircraft to any radar targets observed on the radar display which may be in such proximity to its position or intended route of flight as to warrant its attention.

TRAFFIC PATTERN.—The traffic flow that is prescribed for aircraft landing at, taxiing on, and taking off from an airport. The usual components of a traffic pattern are upwind leg, crosswind leg, downwind leg, base leg, and final approach.

TRANSFERRING CONTROLLER/FACILITY.—A controller/facility transferring control of an aircraft to another controller/facility.

TRANSMISSOMETER.—A direct reading instrument that indicates the visibility in the vicinity of a particular runway, usually the instrument runway.

TRANSPONDER.—An airborne radar beacon receiver-transmitter which automatically receives radio signals from all interrogators on the ground and which selectively replies with a specific reply pulse or pulses group only to those interrogations being received on the mode to which it is set to respond.

TRIGGER.—A sharp voltage pulse usually from 1/2 to 2 microseconds, which is applied to the modulator tubes to fire the transmitter, and simultaneously applied to the sweep generator to start the electron beam moving from the sweep origin to the edge of the scope.

TURBOPROP.—Turbine-engine-driven propeller.

TURBOJET EN ROUTE DESCENT.—A procedure for effecting the descent of military jet aircraft from an en route altitude to the final approach without execution of the maneuvers prescribed in a published high altitude instrument approach procedure. Its purpose is to expedite the movement of air traffic.

TURBULENCE.—Irregular motion of the atmosphere produced when air flows over a comparatively uneven surface, such as the surface of the earth, or when two currents of air flow past or over each other in different direction or at different speeds.

TWEBS.—Transcribed Weather Broadcast Service.

UHF COMMUNICATIONS.—Communications using ultrahigh radiofrequencies.

ULTRAHIGH RADIOFREQUENCY (UHF).—300 to 3,000 megahertz.

USERS.—The various groups of aviation that use the services of the nation's aviation facilities.

VECTOR.—A heading issued to an aircraft to provided navigational guidance by radar.

VFR AIRCRAFT.—An aircraft conducting flight in accordance with Visual Flight Rules.

VFR CONDITIONS.—Basic weather conditions prescribed for flight under Visual Flight Rules.

VFR-ON-TOP.—A type of IFR clearance in which the aircraft may be operated at any altitude at or above the minimum en route altitude (MEA) which is 1,000 feet or more above the cloud layer.

VHF COMMUNICATIONS.—Communications using the very high radiofrequencies.

VIDEO MAPPING.—A method of reproducing a map of the area covered by the radar on the face of the cathode-ray tube or scope. It is electronically fed into the receiving system and displayed on the scope along with any target returns of the radar. The video mapper is synchronized with the antenna rotation so that the video map corresponds to the area covered by the antenna.

VISIBILITY.—The transparency and illumination of the atmosphere as affecting the distance at which objects can be seen.

VISUAL APPROACH.—An approach wherein an aircraft on an IFR flight plan, operating in VFR conditions and having received an air traffic control authorization, may deviate from the prescribed instrument approach procedures and proceed to the airport of destination by visual reference to the surface.

VISUAL FLIGHT RULES (VFR).—Rules prescribed by Federal Aviation Regulations governing visual flight.

VOR.—VHF navigational aid (omnidirectional course information).

VORTAC.—Collocated VOR and TACAN navigational aids (VHF and UHF course and UHF distance information).

WARM AIR MASS.—Broadly speaking, an air mass that is warm relative to neighboring

10729

air masses. The term implies that the air mass originated in latitudes lower than those in which it now finds itself and that it is, therefore, warmer than the surface over which it is moving.

WARM FRONT.—The discontinuity at the forward edge of an advancing current of relatively warm air which is displacing a retreating colder air mass.

WARNING AREA.—An airspace warning area is the same as a Restricted Area but is located outside the United States or its Territories and possessions.

WEATHER ADVISORY.—In aviation weather forecast practice, an expression of anticipated hazardous weather conditions as they affect the operation of air traffic and as prepared by the Weather Bureau.

APPENDIX II

JOINT ELECTRONICS TYPE DESIGNATION SYSTEM

	Set Indicator Letters				
1st letter (designed installation classes)	2d letter (type of equipment)	3d letter (purpose)	Model No.	Modification letter	Miscellaneous identification
Installation	Type of Equipment	Purpose			
A—Piloted aircraft.	A—Invisible light, heat radiation.	A—Auxiliary assemblies (not complete operating sets used with or part of two or more sets or sets series).	1	A	X—Changes in.
B—Underwater mobile, submarine.	C—Carrier.	B—Bombing	2	B	Y—Voltage.
C—Air transportable (inactivated, do not use).	D—Radiac.	C—Communications (receiving and transmitting).	3	C	Z—Phase or frequency.
D—Pilotless carrier.	E—Nupac.	D—Direction finder, reconnaissance, and/or surveillance.	4, etc.	D, etc.	T—Training.
F—Fixed ground.	F—Photographic.	E—Ejection and/or release.			(V)—Variable grouping.
G—Ground, general ground use.	G—Telegraph or teletype.	G—Fire control or searchlight directing.			
K—Amphibious.	I—Interphone and public address.	H—Recording and/or reproducing (graphic, meteorological and sound).			
M—Ground, mobile.	J—Electromechanical or inertial wire covered.	K—Computing.			
P—Portable.	K—Telemetering.				
S—Water surface.	L—Countermeasures.				
T—Ground, transportable.	M—Meteorological.				
U—General utility.	N—Sound in air.				
V—Ground, vehicular.	P—Radar.

Figure 15-11. —E-type T-junction and E field.

transmitter via arm 3, in phase signals must arrive from both directions at this junction (fig. 15-11 (B) (2)).

2. The energy moving clockwise around ring from arm 1 is not sufficient to fire the TR tube in arm 2, and energy passes to the receiver through arm 2. There is a phase reversal (arm 2 presents high Z at the junction with the ring (fig. 15-11 (B) (4)), and the remainder of the energy moves clockwise around the ring to arm 3.

3. The energy moving counterclockwise around the ring from arm 1 is likewise not sufficient to fire the TR tube in arm 4, and energy passes to the receiver through arm 4. There is a phase reversal (fig. 15-11 (B) (4)), and the remainder of the energy moves counterclockwise around the ring to arm 3.

4. At arm 3 the clockwise and counterclockwise components are in phase, and no energy is coupled to the transmitter through arm 3 (fig. 15-11 (B) (2)).

Rules for Hybrid Ring Junctions

Hybrid ring junctions are often given a more colorful name: ratrace. These rings are used to add, subtract, and split up RF energy. They also provide switching of energy into appropriate channels. The hybrid ring junctions consist of a waveguide ring with four arms projecting from it. Each arm can be connected to a waveguide section. In the figures of hybrid ring junctions, the symbols delta (Δ) and sigma (Σ) placed by an arm stand for the difference and the sum respectively, of signal amplitudes of single input signals.

The principle of operation of a hybrid ring can be summarized very briefly by the following rules, which are illustrated in figure 15-12.

1. A signal applied to a Σ (sum) arm will split and leave the ring at two adjacent arms. The output signals will be equal in amplitude, but 180° out of phase with one another.

2. A signal applied to a Δ (difference) arm will split and leave the ring at two adjacent

ABSTRACT - Prepared by the Navy Training Publications Center, this manual is to be used by enlisted naval personnel studying for advancement in the Air Controlman rating. Chapters are: (1) Air Controlman Rating, (2) Flight Planning, (3) Facility Operation, (4) Terminal Instrument Procedures, (5) Air Traffic Control, (6) Emergency Procedures, (7) CVA/CVS Procedures, and (8) Administration. Other information found in this manual are definitions, abbreviations, numerous illustrations, and a list of suggested readings. A related document is available as VT 012 768, also in this issue. AIR CONTROLMAN 1 & C

BUREAU OF NAVAL PERSONNEL

RATE TRAINING MANUAL NAVPERS 10368-D

PREFACE

This Rate Training Manual is one of a series of training manuals prepared especially for the enlisted men of the Navy and Naval Reserve who are studying for advancement in the Air Controlman rating. The manual is based on the professional qualifications for the rates of AC1 and ACC, as set forth in the Manual of Qualifications for Advancement, NavPers 18068 (Series).

Combined with the necessary practical experience and a thorough knowledge of the materials contained in Air Controlman 3 & 2, NavPers 10367-D, completion of the correspondence course based on this manual will greatly assist the AC2 and AC1 in preparing for their advancement examinations. This manual should also be valuable as a refresher for the ACC who is studying for advancement to ACCS and the ACCS who is studying for advancement to ACCM.

This training manual was prepared by the Navy Training Publications Center, Millington, Tennessee, for the Bureau of Naval Personnel. Technical reviews were provided by the Naval Air Technical Training Center, Glynco, Georgia, and the Naval Examining Center, Great Lakes, Illinois.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

READING LIST

United States Armed Forces Institute (USAFI) courses for additional reading and study are available through your Educational Services Officer.* The following courses are recommended:

C 152 General Mathematics II

E 290 Physics I

*"Members of the United States Armed Forces Reserve components, when on active duty, are eligible to enroll for USAFI courses, services, and materials if the orders calling them to active duty specify a period of 120 days or more, or if they have been on active duty for a period of 120 days or more, regardless of the time specified on the active duty orders."

Figure 15-12.—Hybrid ring junctions.

arms. The two output signals from these arms are equal in amplitude and in phase.

3. If in-phase signals are applied to two opposite arms, the output of the adjacent Δ arm will be proportional to the sum of the input signals. The output of the Σ arm will be proportional to the difference of the input signals.

4. If 180° out-of-phase signals are applied to two opposite arms, the output of the adjacent Δ arm will be proportional to the difference of the input signals. The output of the Σ arm will be proportional to the sum of the amplitudes of the input signals.

MONOPULSE COMPARATOR OPERATION

A simplified schematic of the comparator is shown in figure 15-13. To find out how it works, first trace out the energy paths during transmission. Transmitter energy enters the summation arm of HY-1. According to

CHAPTER 1

AIR CONTROLMAN RATING

This training manual is designed to help you to meet the professional qualifications for advancement to First Class and Chief Air Controlman. The Air Controlman qualifications which are used as a guide in the preparation of this manual are current through change 4 of the current revision of the Manual of Qualifications for Advancement, NavPers 18068. Subsequent changes in the qualifications may not be reflected in the information given here.

The remainder of this chapter gives information on the Air Controlman rating, the enlisted rating structure, requirements and procedures for advancement, and references that will help you in preparing for advancement. Information on how to best use Navy Rate Training Manuals is also included. Therefore, it is strongly recommended that you study this chapter carefully before beginning intensive study of the remaining chapters.

ENLISTED RATING STRUCTURE

The present enlisted rating structure includes two types of ratings: general ratings and service ratings.

GENERAL RATINGS are designed to provide paths of advancement and career development. A general rating identifies a broad occupational field of related duties and functions requiring similar aptitudes and qualifications. General ratings provide the primary means used to identify billet requirements and personnel qualifications. Some general ratings include service ratings; others do not. Both Regular Navy and Naval Reserve personnel may hold general ratings.

Subdivisions of certain general ratings are identified as SERVICE RATINGS. These service ratings identify areas of specialization within the scope of a general rating. Service ratings are established in those general ratings in which specialization is essential for efficient utilization of personnel. Although service ratings can exist at any petty officer level, they are most common at the PO3 and PO2 levels. Both Regular Navy and Naval Reserve personnel may hold service ratings.

AC RATING

The Air Controlman rating is a general rating and is included in Navy Occupational Group IX (Aviation). There are no AC service ratings.

Before an individual can be recommended for any Air Controlman rating, he must possess the following as minimum qualification:

1. A certificate indicating successful completion of the FAA basic airman written examination for air traffic controllers.
2. A Class II FAA medical certificate.

Figure 1-1 illustrates the path of advancement from Recruit to Master Chief Air Controlman, Warrant Officer, and Limited Duty Officer. BuPers Instruction 1120.18 (Series) provides guidance for submission of application for promotion to Warrant Officer and Limited Duty Officer.

Shaded areas in figure 1-1 indicate career stages from which qualified enlisted men may advance to Warrant Officer (W-1), and selected Commissioned Warrant Officers (W-2 and W-3) may advance to Limited Duty Officer.

Unlike the civilian counterpart, the Navy Air Controlman is not a specialized Center Controller, Tower Controller, or a Flight Service Specialist. The Navy AC is required to be

10748

10747

AC.1

Figure 1-1.—Paths of advancement.

10748

a professional air traffic controller, knowledgeable in all areas of air traffic control and a professional military man who transfers at regular intervals.

This point may be accented by a brief description of the types of duty which an Air Controlman may expect to receive or that he may request as follows:

1. Naval air stations.

a. AC's assigned to air stations are normally attached to the Air Traffic Control division within the operations department. AC1's and ACC's normally serve as watch supervisors or branch supervisors and normally have several personnel under their supervision performing the various air traffic control duties.

b. The AC1 or ACC performs supervisory and ATC functions in control towers, radar air traffic control centers, ground controlled approach units, and flight clearance offices. Tools of the trade include radio, radar, direction finding equipment, teletype, and various forms of direct line telephone equipment.

c. They control air traffic under all types of weather conditions, assist in the administration of the ATC division and ATC function of the naval air station, process flight plans and clearances, keep appropriate records as basis for reports required, and maintain current flight planning and related information.

2. CVA/CVS's

a. Air Controlmen assigned aboard aircraft carriers may be members of the CCA team or the Air Operations crew, both of which make up the CATCC.

b. AC's perform basically the same type duties aboard ship as described for naval air stations, adapted to the mobility aspect of aircraft carriers and the increased tempo and precision required for aircraft operations at sea.

3. LPH's

a. Air Controlmen are assigned aboard each of the LPH's.

b. They perform communications and air traffic control service, including the use of radar.

4. Instructor billets.

a. AC "A" and "B" schools, and CATCC and GCA "C" operator schools, all located at NAS Glynco, Georgia.

b. The technical advisor/writer for the Air Controlman Rate Training Manuals located at the Navy Training Publications Center, Millington, Tenn.

c. The item writer for Air Controlman fleet-wide rating exams, located at the Naval Examining Center, Great Lakes.

d. One billet exists at each of the Navy Regional Airspace Offices (NARASPO) which correspond to the FAA regions dealing with problems concerning the use of airspace for Navy air traffic control.

e. The Fleet Computer Training Center, San Diego.

f. The Office of the CNO (OP-534) having to do with airspace matters in liaison with the regional NARASPO's.

g. Naval Safety Center as a technical expert on air traffic control matters.

h. Fleet Antiaircraft Warfare Training Center in the CCA mockup portion of the training program.

i. COMNAVAIRPAC and COMNAVAIR LANT duty as instructors for the automatic carrier landing system.

5. Miscellaneous Billets.

a. Radar bomb sites or bomb ranges where senior AC's act as range safety officers and others act as spotters, observers, etc.

b. The White House Staff having to do with the movement of helicopters to and from the White House lawn.

c. Recruiting duty for second class AC's and above. The criteria for selection for these billets stress military pride and performance and uniform perfection.

d. Wave Air Controlmen may get duty at the Wave Recruit Training Center.

e. San Nicholas Island in support of the Point Mugu missile range.

f. San Clemente Island in support of the Sea Lab operations.

g. Naval Air Tactical Control Squadrons to perform the various functions relating to control of aircraft in amphibious operations.

You can see by this varied list of duties and duty stations available the variety of positions of responsibility the AC's may occupy.

The technical assistant to the AC rating control officer in the Bureau of Personnel (BuPers 2144) is an ACCM. He can provide more or detailed information on the billets described and can be reached by phone or correspondence.

10750

10749

The Naval Enlisted Classifications Codes for the AC rating are as follows:

1. AC-6900 is an Entry Series NEC and is assigned to E-2 and E-3 personnel in training as AC's and who are not designated strikers.
2. AC-6922 identifies a GCA Controller and is assigned to a GCA operator school graduate.
3. AC-6912 identifies a CCA Controller. This code may be assigned to a CATCC school graduate upon recommendation of the commanding officer after qualification as a final controller and one other of the following:
   a. Approach Controller.
   b. Marshal Controller.
   c. Wave-Off/Bolter Controller.
   d. Departure Controller.

An AC must be an AC-6922 to be eligible for AC-6912.

4. AC-6911 indentifies a CATCC Supervisor. To be assigned AC-6911, an AC must be qualified in all CATCC operator positions (hence be an AC-6912), be able to supervise and direct the operation of the CATCC, and be recommended by the commanding officer.

Air Controlmen that do not fall within the above classifications may be assigned 0000 or a Special Series NEC such as one which designates instructors.

SUPERVISORY SKILLS

As you advance in rating, more of your work becomes a matter of supervision and training others in the performance of the various functions of the air traffic control facility. Your value to the organization will be measured largely in terms of the quality of work of your subordinates. This does not mean that everything can be delegated to subordinates, as there will continue to be tasks and responsibilities that you must take care of yourself. However, you must not take the attitude that it is easier to do the work than to train and supervise someone else.

Supervision is being responsible for and directing the work of others. In supervising your subordinates, you will need to have certain skills and knowledge. A supervisor is a manager; therefore, he should be well versed in the principles of management. The material presented here is for a twofold purpose: First, to acquaint you with the basic principles so that your first supervisory duties will get off to a good start; and second, to give you a basis from which to build as you progress toward the higher ratings.

The supervisor needs to know and be skilled in the following factors to effectively supervise the men under him:

1. Skill in leading.
2. Skill in organizing.
3. Knowledge of his work.
4. Knowledge of his responsibilities.
5. Skill in communicating ideas.
6. Skill in instructing.
7. Problem solving.

Skill in Leading

Here is where you should excel. Lead the men that you are coaching, do not drive them. Set examples for them to follow. Know them as individuals and handle their problems individually. Reprimand them in private; praise them in public. The men will work for you, and their training will be more easily accomplished and more effective if you can learn to (1) be predictable and consistent in your dealings with them, (2) project to your men the enthusiasm you feel for the work they are doing, and (3) have no fear of your position, your boss, the people you are supervising, and tough jobs, or honest mistakes.

This is not an all-inclusive list of things that will make you a leader of men overnight. These items are sound, basic principles that, when mixed well with common sense, will improve your leadership abilities.

Skill in Organizing

Another skill needed in supervision is skill in organizing. Organization is a form of discipline which, if carefully accomplished, can contribute substantially to successful supervision.

An important element of good organization is the delegation of AUTHORITY and RESPONSIBILITY, which must always go together. It has been said that the ideal of sound organization should be to fix responsibility as low in the organization as competence exists to assume the responsibility. Many individuals are reluctant to delegate authority because they fear the possibility of being embarrassed by the acts of

their subordinates. These fears are generally an indication of a feeling of insecurity on the part of the supervisor. This insecure feeling can best be overcome by training the subordinates to increase their capacity for accepting responsibility and authority.

Not only do supervisors sometimes fail to delegate authority, but they also frequently fail to delegate properly the work that needs to be done. A supervisor can very readily handicap himself by trying to do more than he needs to do. The result is that he becomes an ineffective supervisor and leader.

Knowledge Required

Successful supervision demands a vast amount of knowledge. The wide variety and complexity of jobs require the supervisor to have considerable technical knowledge. It is inevitable, however, that the supervisor will be given some tasks for which his training and experience are inadequate. In these situations the supervisor must be dependent upon the knowledge and abilities of others, and upon his own leadership.

The supervisor must have a knowledge of the overall objectives of the organization of which he is a part. In addition, he needs to have a clear understanding of the specific part his own group must play in attaining the basic goals. His planning, organization, directing, and, in fact, all problem solving should be done with both the general and specific aims of the organization clearly in mind.

Knowledge of Men as Individuals

Of paramount importance to a successful supervisor is a thorough knowledge of the subordinates as individuals. The supervisor needs to be continuously aware of the fact that individual differences do exist and that they cannot be overlooked.

It is particularly dangerous for a supervisor to fall into the habit of stereotyping people.

Skill in the Communication of Ideas

Another skill which is required of a good supervisor is skill in the communication of ideas. This is essential in giving orders, in the dissemination of information, and in training or teaching. In the Navy, the channels for communication and the lines of authority are the same. These channels should not be bypassed. If one's subordinates are expected to function willingly and cooperatively, they should be given all the information they need or can use.

Skills in Instructing

The actual development of a training program is discussed in a later chapter. The apprentice is depending on you to demonstrate and coach him in the correct procedures and methods to be used. You must develop skill in imparting your knowledge to trainees on how the job is to be done. As the trainee progresses from one work experience to another, you will be guiding and coaching him. To assist you in developing skill in instructing, keep the following in mind:

1. Show your new man how to do the job without showing off or showing him up.
2. Have all the answers you can, admit it when you do not, and get him the correct answer as soon as possible.
3. Learn to be sincerely interested in others.
4. Keep your sense of humor.
5. Be patient.
6. Be sure the trainee understands what the job is and how it is to be done.

Problem Solving

The practical exercise of supervision (or leadership) is largely concerned with problem solving. Every day new problems are encountered; there are difficulties different from any you have ever met. If you can look at these difficulties briefly, and then, almost without pause, see and apply a sound solution, you are fortunate. Indeed, you are exceptional; for most of us must cautiously examine difficult problems and weigh the solutions carefully. Even then, we are subject to serious errors if we overlook some of the details which are not too obvious.

If all of us were to go about solving problems in exactly the same manner, we would necessarily have exactly the same thought processes. Although we do not think alike, all those who are capable of finding proper solutions quickly and easily do have something in common. They follow a fairly well established pattern of thought and action.

10751

Some people practice the pattern instinctively, thereby reaching solid, useful conclusions in what appears to be an amazingly short time. For most of us, this pattern is not one we know instinctively. We learn it only after having paid in concerted effort. We may lean of it in the classroom, on the job, or from books, but it becomes a habit only after the trial and error of repeated application.

TECHNIQUES IN PROBLEM SOLVING.—The problem solving process may be divided into six steps. Individual leaders go through these steps either deliberately or automatically.

Preliminary to solving a problem, you must recognize that there is an actual problem to be solved. Then you proceed as follows:

1. Define the problem.
2. Establish objectives. By this is meant what do you want to accomplish.
3. Get the facts. Assemble all the facts pertinent to the problem. Ascertain what personnel, if any, are involved. Review the record. Find out what rules, regulations, and customs apply. Contact the individual concerned for opinions and feelings, as well as facts. Be sure you have the whole story. Perhaps materials or equipment constitute a part of the problem. Methods or operational schedules may also affect the problem.
4. Weigh and decide. After all the facts have been assembled, analyze the problem in light of the facts. Fit the facts together and consider their bearing on each other. Check regulations, policies, and practices. What possible actions are there? What are the possible results of each action? Choose the best action, but do not make sudden or quick conclusions.
5. Take action. First consider the following questions: Should I handle this problem myself? Do I need any help in handling it? Then consider the proper time and place to take the action that appears most likely to solve the problem. Do not depend on someone else to solve the problem.
6. Evaluate the action. In this step, check the results of your action to see if it solved the problem. Never just assume that the problem was solved, as you may find that the action brought about additional problems instead of solving the initial problem. Watch for changes in output, attitudes, and relationships. If the problem was not solved, you may need to gather more facts and go through the entire problem solving procedure again.

The problem solving technique can be mastered by any individual who is capable of learning. It may seem to take a great deal of time, but eventually it will actually save time. The individual who desires to become a good supervisor should become so skilled in its use that this technique is used automatically when dealing with the problems of supervision.

ADVANCEMENT

By this time, you are probably well aware of the personal advantages of advancement—higher pay, greater prestige, more interesting and challenging work, and the satisfaction of getting ahead in your chosen career. By this time, also, you have probably discovered that one of the most enduring rewards of advancement is the training you acquire in the process of preparing for advancement.

The Navy also profits by your advancement. Highly trained personnel are essential to the functioning of the Navy. By advancement, you increase your value to the Navy in two ways: First, you become more valuable as a technical specialist, and thus make far-reaching contributions to the entire Navy; and second, you become more valuable as a person who can supervise, lead, and train others.

Since you are studying for advancement to PO1 or CPO, you are probably already familiar with the requirements and procedures for advancement. However, you may find it helpful to read the following sections. The Navy does not stand still. Things change all the time, and it is possible that some of the requirements have changed since the last time you went up for advancement. Futhermore, you will be responsible for training others for advancement; therefore, you will need to know the requirements in some detail.

HOW TO QUALIFY FOR ADVANCEMENT

To qualify for advancement, a person must:

1. Have a certain amount of time in grade.
2. Complete the required Rate Training Manuals either by demonstrating a knowledge of the material in the manual by passing a locally prepared and administered test or by passing the Enlisted Correspondence Course based on the Rate Training Manual.

10752

3. Demonstrate the ability to perform all the PRACTICAL requirements for advancement by completing applicable portions of the Record of Practical Factors, NavPers 1414/1.

4. Be recommended by your commanding officer, after the petty officers and officers supervising your work have indicated that they consider you capable of performing the duties of the next higher rate.

5. Demonstrate KNOWLEDGE by passing a written examination on (a) military requirements, and (b) professional qualifications.

Some of these general requirements may be modified in certain ways. Figure 1-2 gives an overall view of the requirements for advancement of active duty personnel; figure 1-3 gives this information for inactive duty personnel.

Remember that the requirements for advancement can change. Check with your educational services office to be sure that you know the most recent requirements.

When you are training lower rated personnel, it is a good idea to point out that advancement is not automatic. Meeting all the requirements makes a person ELIGIBLE for advancement, but it does not guarantee his advancement. Such factors as the score made on the written examination, length of time in service, performance marks, and quotas for the rating enter into the final determination of who will actually be advanced.

HOW TO PREPARE FOR ADVANCEMENT

What must you do to prepare for advancement? You must study the qualifications for advancement, work on the practical factors, study the required Rate Training Manuals, and study other material that is required. You will need to be familiar with the following:

1. Manual of Qualifications for Advancement, NavPers 18068 (Series).
2. Record of Practical Factors, NavPers 1414/1.
3. Training Publications for Advancement, NavPers 10052 (Series).
4. Applicable Rate Training Manuals and their companion Enlisted Correspondence Courses.

Collectively, these documents make up an integrated training package tied together by the qualifications. The following paragraphs describe these materials and give some information on how each one is related to the others.

"Quals" Manual

The Manual of Qualifications for Advancement, NavPers 18068 (series), gives the minimum requirements for advancement to each rate within each rating. This manual is usually called the "Quals" Manual, and the qualifications themselves are often called "quals." The qualifications are of two general types: (1) military requirements, and (2) professional or technical qualifications. Military requirements apply to all ratings rather than to any one rating alone. Professional qualifications are technical or professional requirements that are directly related to the work of each rating.

Both the military requirements and the professional qualifications are divided into subject matter groups. Then, within each subject matter group, they are divided into PRACTICAL FACTORS and KNOWLEDGE FACTORS.

The qualifications for advancement and a bibliography of study materials are available in your educational services office. The "Quals" Manual is changed more frequently than Rate Training Manuals are revised. By the time you are studying this training manual, the "quals" for your rating may have been changed. Never trust any set of "quals" until you have checked the change number against an UP-TO-DATE copy of the "Quals" Manual.

In training others for advancement, emphasize these three points about the "quals":

1. The "quals" are the MINIMUM requirements for advancement. Personnel who study MORE than the required minimum will have a great advantage when they take the written examinations for advancement.
2. Each "qual" has a designated rate level—chief, first class, second class, or third class. You are responsible for meeting all "quals" specified for the rate level to which you are seeking advancement AND all "quals" specified for lower rate levels.
3. The written examinations for advancement will contain questions relating to the practical factors AND to the knowledge factors of BOTH the military requirements and the professional qualifications.

10753

REQUIREMENTS*	E1 to E2	E2 to E3	#† E3 to E4	#E4 to E5	† E5 to E6	† E6 to E7	† E7 to E8	† E8 to E9

ENLISTED PERFORMANCE EVALUATION	As used by CO when approving advancement.		Counts toward performance factor credit in advancement multiple.					
EXAMINATIONS**	Locally prepared tests.	See below.	Navy-wide examinations required for all PO advancements.				Navy-wide, selection board.	
RATE TRAINING MANUAL (INCLUDING MILITARY REQUIREMENTS)		Required for E-3 and all PO advancements unless waived because of school completion, but need not be repeated if identical course has already been completed. See NavPers 10052 (current edition).					Correspondence courses and recommended reading. See NavPers 10052 (current edition).	
AUTHORIZATION	Commanding Officer		Naval Examining Center					

* All advancements require commanding officer's recommendation.
† 1 year obligated service required for E-5 and E-6; 2 years for E-6, E-7, E-8 and E-9.
# Military leadership exam required for E-4 and E-5.
** For E-2 to E-3, NAVEXAMCEN exams or locally prepared tests may be used.
†† Waived for qualified EOD personnel.

Figure 1-2.—Active duty advancement requirements.

CC-9754

REQUIREMENTS *	E1 to E2	E2 to E3	E3 to E4	E4 to E5	E5 to E6	E6 to E7	E8	E9
TOTAL TIME IN GRADE	4 mos.	6 mos.	6 mos.	12 mos.	24 mos.	36 mos.	36 mos.	24 mos.
TOTAL TRAINING DUTY IN GRADE †	14 days	14 days	14 days	14 days	28 days	42 days	42 days	28 days
PERFORMANCE TESTS			Specified ratings must complete applicable performance tests before taking examination.					
DRILL PARTICIPATION	Satisfactory participation as a member of a drill unit in accordance with BUPERSINST 5400.42 series.							
PRACTICAL FACTORS (INCLUDING MILITARY REQUIREMENTS)	Record of Practical Factors, NavPers 1414/1, must be completed for all advancements.							
RATE TRAINING MANUAL (INCLUDING MILITARY REQUIREMENTS)	Completion of applicable course or courses must be entered in service record.							
EXAMINATION	Standard Exam		Standard Exam required for all PO Advancements. Also pass Military Leadership Exam for E-4 and E-5.				Standard Exam, Selection Board.	
AUTHORIZATION	Commanding Officer		Naval Examining Center					

* Recommendation by commanding officer required for all advancements.

† Active duty periods may be substituted for training duty.

Figure 1-3.—Inactive duty advancement requirements.

10755

Record of Practical Factors

Before you can take the Navy-wide examination for advancement, there must be an entry in your service record to show that you have qualified in the practical factors of both the military requirements and the professional qualifications. A special form known as the Record of Practical Factors, NavPers 1414/1 (plus the abbreviation of the appropriate rating), is used to keep a record of your practical factor qualifications. The form lists all practical factors, both military and professional. As you demonstrate your ability to perform each practical factor, appropriate entries are made in the DATE and INITIALS columns.

As a PO1 or CPO, you will often be required to check the practical factor performance of lower rated personnel and to report the results to your supervising officer.

As changes are made periodically to the "Quals" Manual, new forms of NavPers 1414/1 are provided when necessary. Extra space is allowed on the Record of Practical Factors for entering additional practical factors as they are published in changes to the "Quals" Manual. The Record of Practical Factors also provides space for recording demonstrated proficiency in skill which are within the general scope of the rating but which are not identified as minimum qualifications for advancement. Keep this in mind when you are training and supervising other personnel. If a person demonstrates proficiency in some skill which is not listed in the "quals" but which is within the general scope of the rating, report this fact to the supervising officer so that an appropriate entry can be made in the Record of Practical Factors.

When you are transferred, the Record of Practical Factors should be forwarded with your service record to your next duty station. It is a good idea to check and be sure that this form is actually instered in your service record before you are transferred. If the form is not in your record, you may be required to start all over again and requalify in practical factors that have already been checked off. You should also take some responsibility for helping lower rated personnel keep track of their practical factor records when they are transferred.

A second copy of the Record of Practical Factors should be made available to each man in pay grades E-2 through E-8 for his personal record and guidance.

The importance of NavPers 1414/1 cannot be over-emphasized. It serves as a record to indicate to the petty officers and officers supervising your work that you have demonstrated proficiency in the performance of the indicated practical factors and is part of the criteria utilized by your commanding officer when he considers recommending you for advancement. In addition, the proficient demonstration of the applicable practical factors listed on this form can aid you in preparing for the examination for advancement. Remember that the knowledge aspects of the practical factors are covered in the examination for advancement. Certain knowledge is required to demonstrate these practical factors and additional knowledge can be acquired during the demonstration. Knowledge factors pertain to that knowledge which is required to perform a certain job. In other words, the knowledge factors required for a certain rating depend upon the jobs (practical factors) that must be performed by personnel of that rating. Therefore, the knowledge required to proficiently demonstrate these practical factors will definitely aid you in preparing for the examination for advancement.

NavPers 10052

Training Publications for Advancement, NavPers 10052 (Series) is a very important publication for anyone preparing for advancement. This publication/bibliography lists required and recommended Rate Training Manuals and other reference material to be used by personnel working for advancement. NavPers 10052 (Series) is revised and issued once each year by the Bureau of Naval Personnel. Each revised edition is identified by a letter following the NavPers number; be SURE you have the most recent edtion.

The required and recommended references are listed by rate level in NavPers 10052 (Series). It is important to remember that you are responsible for all references at lower rate levels, as well as those listed for the rate to which you are seeking advancement.

Rate Training Manuals that are marked with an asterisk (*) in NavPers 10052 (Series) are MANDATORY at the indicated rate levels. A mandatory training manual may be completed by (1) passing the appropriate Enlisted Correspondence Course that is based on the mandatory training manual; (2) passing locally

10756

the rule 1, the signal splits and leaves the ring at the two adjacent arms. These two signals have the same amplitude, but are 180° out of phase. Then the signals are fed to the summation arms of hybrid rings HY-2 and HY-3. The waveguide lengths between HY-1 and HY-2, and HY-1 and HY-3 are equal; hence the signals enter the rings simultaneously. Again keeping in mind rule 1, the signals in HY-2 and HY-3 divide their energy equally and out of phase with each other. The energy, now divided into four separate signals, is sent to the horn cluster. By varying the waveguide sections between the hybrid rings and horns, the separate signals will arrive at each horn in phase with one another. The energy radiated from the horns combines to form a single wave front. The radiated energy is focused into a narrow circular beam by the lens antenna. Energy does not pass through the difference arms of HY-1, HY-2, and HY-3 because the signals are canceled at these junctions by proper waveguide matching. If energy were allowed to pass through these arms, it would burn out the mixer crystals, and possibly the receiver.

Echo returns are focused by the lens into the four horns. The amount of energy entering each horn is determined by the position of the target with respect to the antenna axis. Phase inversion of the energy takes place due to the lens. Returned energy is combined in the four hybrid rings of the comparator. The comparator compares the amplitude of the energy in each horn, and produces a sum signal and two difference signals. The sum signal is used for ranging and also provides a reference for the elevation and traverse tracking channels.

The sum or range signal is composed of signals from all four feed horns added together in phase. Since the radar's range system is only interested in the presence of the target in the beam, and not in the target's relative position within the beams, the sum of all the energy received is used in ranging to insure maximum detection capability. The sum signal

Figure 15-13. —Microwave comparator.

1073

prepared tests based on the information given in the mandatory training manual; or (3) in some cases, successfully completing an appropriate Navy school.

When training personnel for advancement, do not overlook the section of NavPers 10052 (Series) which lists the required and recommended references relating to the military requirements for advancement. All personnel must complete the mandatory military requirements training manual for the appropriate rate level before they can be eligible to advance. Also, make sure that personnel working for advancement study the references listed as recommended but not mandatory in NavPers 10052 (Series). It is important to remember that ALL references listed in NavPers 10052 (Series) may be used as source material for the written examinations, at the appropriate levels.

Rate Training Manuals

There are two general types of Rate Training Manuals. Rate Training Manuals (such as this one) are prepared for most enlisted rates and ratings, giving information that is directly related to the professional qualifications for advancement. Subject matter manuals give information that applies to more than one rating.

Rate Training Manuals are revised from time to time to bring them up to date technically. The revision of a Rate Training Manual is identified by a letter following the NavPers number. You can tell whether a Rate Training Manual is the latest edition by checking the NavPers number (and the letter following the number) in the most recent edition of List of Training Manuals and Correspondence Courses, NavPers 10061 (Series). (NavPers 10061 is actually a catalog that lists current training manuals and correspondence courses; you will find this catalog useful in planning your study program.)

Rate Training Manuals are designed for the special purpose of helping naval personnel prepare for advancement. By this time, you have probably developed your own way of studying these manuals. Some of the personnel you train, however, may need guidance in the use of Rate Training Manuals. Although there is no single "best" way to study a training manual, the following suggestions have proved useful for many people:

1. Study the military requirements and the professional qualifications for your rate before you study the training manual, and refer to the "quals" frequently as you study. Remember, you are studying the training manual primarily to meet these "quals."

2. Set up a regular study plan. If possible, schedule your studying for a time of day when you will not have too many interruptions or distractions.

3. Before you begin to study any part of the training manual intensively, get acquainted with the entire manual. Read the preface and the table of contents. Check through the index. Thumb through the manual without any particular plan, looking at the illustrations and reading bits here and there as you see things that interest you.

4. Look at the training manual in more detail, to see how it is organized. Look at the table of contents again. Then, chapter by chapter, read the introduction, the headings, and the subheadings. This will give you a clear picture of the scope and content of the manual.

5. When you have a general idea of what is in the training manual and how it is organized, fill in the details by intensive study. In each study period, try to cover a complete unit—it may be a chapter, a section of a chapter, or a subsection. The amount of material you can cover at one time will vary. If you know the subject well, or if the material is easy, you can cover quite a lot at one time. Difficult or unfamiliar material will require more study time.

6. In studying each unit, write down questions as they occur to you. Many people find it helpful to make a written outline of the unit as they study, or at least to write down the most important ideas.

7. As you study, relate the information in the training manual to the knowledge you already have. When you read about a process, a skill, or a situation, ask yourself some questions. Does this information tie in with past experience? Or is this something new and different? How does this information relate to the qualifications for advancement?

8. When you have finished studying a unit, take time out to see what you have learned. Look back over your notes and questions. Maybe some of your questions have been answered, but perhaps you still have some that are not answered. Without referring to the training manual, write down the main ideas you have

8210757

learned from studying this unit. Do not just quote the manual. If you cannot give these ideas in your own words, the chances are that you have not really mastered the information.

9. Use Enlisted Correspondence Courses whenever you can. The correspondence courses are based on Rate Training Manuals or other appropriate texts. As mentioned before, completion of a mandatory Rate Training Manual can be accomplished by passing an Enlisted Correspondence Course based on the training manual. You will probably find it helpful to take other correspondence courses, as well as those based on mandatory training manuals. Taking a correspondence course helps you to master the information given in the training manual, and also gives you an idea of how much you have learned.

INCREASED RESPONSIBILITIES

When you assumed the duties of a PO3, you began to accept a certain amount of responsibility for the work of others. With each advancement, you accept an increasing responsibility in military matters and in matters relating to the professional work of your rate. When you advance to PO1 or CPO, you will find a noticeable increase in your responsiblities for leadership, supervision, training, working with others, and keeping up with new developments.

As your responsibilities increase, your ability to communicate clearly and effectively must also increase. The simplest and most direct means of communication is a common language. The basic requirement for effective communication is therefore a knowledge of your own language. Use correct language in speaking and in writing. Remember that the basic purpose of all communcation is understanding. To lead, supervise, and train others, you must be able to speak and write in such a way that others can understand exactly what you mean.

Leadership and Supervision

As a PO1 or CPO, you will be regarded as a leader and supervisor. Both officers and enlisted personnel will expect you to translate the general orders given by officers into detailed, practical, on-the-job language that can be understood and followed by relatively inexperienced personnel. In dealing with your juniors, it is up to you to see that they perform their jobs correctly. At the same time, you must be able to explain to officers any important problems or needs of enlisted personnel. In all military and professional matters, your responsibilities will extend both upward and downward.

Along with your increased responsibilities, you will also have increased authority. Officers and petty officers have POSITIONAL authority—that is, their authority over others lies in their positions. If your CO is relieved, for example, he no longer has the degree of authority over you that he had while he was your CO, although he still retains the military authority that all seniors have over subordinates. As a PO1, you will have some degree of positional authority; as a CPO, you will have even more. When exercising your authority, remember that it is positional—it is the rate you have, rather than the person you are, that gives you this authority.

A Petty Officer conscientiously and proudly exercises his authority to carry out the responsibilities he is given. He takes a personal interest in the success of both sides of the chain of command . . . authority and responsibility. For it is true that the Petty Officer who does not seek out and accept responsibility, loses his authority and then the responsibility he thinks he deservies. He must be sure, by his example and by his instruction, the the Petty Officers under him also accept responsibility. In short, he must be the leader his title—Petty Officer—says he is.

Training

As a PO1 or CPO, you will have regular and continuing responsibilities for training others. Even if you are lucky enough to have a group of subordinates who are all highly skilled and well trained, you will find that training is necessary. For example, you will always be responsible for training lower rated personnel for advancement. Also, some of your best workers may be transferred; and inexperienced or poorly trained personnel may be assigned to you. A particular job may call for skills that none of your personnel have. These and similar problems require that you be a training specialist—one who can conduct formal and informal training programs to qualify personnel for advancement,

58

need arises. When using any publication that is subject to revision, make sure that you have the latest edition. When using any publication that is kept current by means of changes, be sure you have a copy in which all official changes have been made.

The reading list at the beginning of this manual consists of USAFI courses that offer additional background material. The educational services officer will always have the most up-to-date information and training manuals applicable to your rating.

In addition to training manuals and publications, training films furnish a valuable source of supplementary information. Films that may be helpful are listed in the U. S. Navy Film Catalog, NavAir 10-1-777.

ADVANCEMENT OPPORTUNITIES FOR PETTY OFFICERS

Making chief is not the end of the line as far as advancement is concerned. Proficiency pay, advancement to Senior (E-8) and Master (E-9) Chief, and advancement to Warrant Officer and Commissioned Officer are among the opportunities that are available to qualified petty officers. These special paths of advancement are open to personnel who have demonstrated outstanding professional ability, the highest order of leadership and military responsibility, and unquestionable moral integrity.

PROFICIENCY PAY

The Career Compensation Act of 1949, as amended, provides for the award of proficiency pay to designated enlisted personnel who possess special proficiency in military skill. Proficiency pay is given in addition to regular pay and allowances and any special or incentive pay to which you are entitled. Certain enlisted personnel in pay grades E-4 through E-9 are eligible for proficiency pay. Proficiency pay is allocated by ratings and NEC's, with most awards being given in the ratings and NEC's which are designated as critical. The eligibility requirements for proficiency pay are subject to change. In general, however, you must be recommended by your commanding officer, have a certain length of time on continous active duty, and be career designated.

ADVANCEMENT TO SENIOR AND MASTER CHIEF

Chief petty officers may qualify for the advanced grades of Senior and Master Chief which are now provided in the enlisted pay structure. These advanced grades provide for substantial increases in pay, together with increased responsibilities and additional prestige. The requirements for advancement to Senior and Master Chief are subject to change but, in general, include a certain length of time in grade, a certain length of time in the naval service, a recommendation by the commanding officer, and a sufficiently high mark on the Navy-wide examination. The final selection for Senior and Master Chief is made by a regularly convened selection board.

Examination Subjects

Qualifications for advancement to Senior Chief Petty Officer and Master Chief Petty Officer have been developed and published in the Manual of Qualifications for Advancement, NavPers 18068 (Series). They officially establish minimum military and professional qualifications for Senior and Master Chief Petty Officers.

Training Publications for Advancement, Nav Pers 10052 (Series) contains a list of study references which may be used to study for both military and professional requirements.

The satisfactory completion of the correspondence course titled Navy Regulations, Nav Pers 10740-A4, is mandatory for advancement to E-8, and the course titled Military Justice in the Navy, NavPers 10993-A, is required of all personnel advancing to E-9.

ADVANCEMENT TO WARRANT AND COMMISSIONED OFFICER

The Warrant Officer program provides opportunity for advancement to warrant rank for E-6 and above enlisted personnel. E-6's, to be eligible, must have passed an E-7 rating exam prior to selection.

The LDO program provides a path of advancement from warrant officer to commissioned officer. LDO's are limited, as are warrants, in their duty, to the broad technical fields associated with their former rating.

e35960

If interested in becoming a warrant or commissioned officer, ask your educational services officer for the latest requirements that apply to your particular case.

10761
10761

CHAPTER 2

FLIGHT PLANNING

Except in emergencies and flights of combat necessity wherein conditions do not permit, pilots must insure that all preflight planning required for the prosecution of a safe and properly conducted flight has been accomplished prior to carrying out any type of flight in a naval aircraft.

Inadequate preflight planning has been, in some instances, responsible for aircraft accidents. Safety is not an inherent quality in any profession. It is one quality that is achieved by process and is based largely on accumulated knowledge and experience. To a greater extent than is generally realized, unfortunate experiences in the air can be avoided by increasing the overall knowledge and familiarity with each phase of flight planning by Air Controlmen and pilots alike. In short, there is no compromise for good, adequate flight planning.

The thoroughness of flight planning by pilots before takeoff can contribute immeasurably to all-around safety, comfort, and success of any flight, and to the task of preventing accidents. To aid in the safety and efficiency of a flight, pilots must rely to a varying extent upon the assistance provided by the Air Controlmen.

FLIGHT CLEARANCE AUTHORITIES

CLEARANCE AUTHORITY AT NAVAL ACTIVITIES

The authority and responsibility for clearance of aircraft flights at naval activities are vested in the following, who must be guided by existing orders and regulations:

1. Commanding general, commanding officer, or officer in charge of:
   a. Naval air stations.
   b. Marine Corps air stations.
   c. Coast Guard air stations.
   d. Naval auxiliary air stations.
   e. Naval air facilities.
   f. Marine Corps air facilities.
   g. Marine Corps auxiliary air stations.
   h. Auxiliary landing field.
   i. Outlying landing field.

2. The senior naval aviator attached to a naval station having aircraft operating facilities.

3. Fleet Air Detachment Commanders, Marine Aircraft Group Commanders, and the Commanding Officers of NARTU's may clear aircraft under their cognizance based at the naval air activity to which they are assigned. They may delegate authority for clearance of local flights to commanding officers of their units when weather conditions are at or above the IFR minimums specified for IFR clearance of naval aircraft in OpNav 3710.7 (Series) and are forecast to remain at or above these minimums for the duration of the flight. When weather conditions are below such IFR minimums or are forecast to go below those minimums, and operational commitments dictate, clearance of fleet aircraft rests with the cognizant Commander Fleet Air Detachment. Fleet aircraft are subject to local traffic procedures and tower control. Liaison and coordination must be established with the commanding officer of the naval air activity to insure orderly flight clearance procedures.

Pilots holding a valid Special Instrument Rating are authorized to approve flight clearance for any flight of a naval aircraft in which they fly as pilot in command or as flight leader of a formation of aircraft. This may not be construed as authorization to clear members of a flight in weather conditions below the minimums for the type instrument rating held by the individual pilots of the flight.

10762

CLEARANCE AUTHORITY OF PILOT IN COMMAND

When not at a naval activity, or when locally furnished flight clearance facilities are not available at the place of filing, or when in-flight deviation from the initial flight clearance is required, the pilot in command of a naval aircraft is authorized to approve as clearance authority the flight plan for his proposed flight or modification thereof. Appropriate air traffic control regulations must be observed and facilities of Flight Service Stations should be utilized.

DELEGATION OF AUTHORITY

The clearance authorities previously stated may delegate clearance authority to commissioned officers, warrant officers, and naval aviation pilots under their command whom they consider qualified to exercise such authority

GENERAL RESPONSIBILITIES OF CLEARANCE AUTHORITIES

While the actual responsibility for approving flight plans submitted to flight clearance offices normally applies to the operations duty officer, senior AC's working in these offices are in a position to be of great help to the duty officer by checking flight plans for correctness and completeness and bringing any discrepancies to his attention. Knowing your immediate superior's responsibilities is a principle of good leadership, and by actions based on your knowledge of flight clearance procedures you are setting an example for the men who work with and for you.

Flight Clearance Approval Procedures

The clearance authority must insure that all portions of the flight clearance form are complete and that the aircraft is not cleared on a flight that will violate known instructions. The clearing authority should be particularly alert to the following:

1. Pilot in command has signed.
2. The crew is listed on the DD-175. Passengers may be listed on the DD-175 or on a separate passenger manifest.
3. The route of flight section is listed in the proper code to indicate selected navigation fixes.
4. Fuel reserve is sufficient for the flight. Aircraft must carry sufficient usable fuel, considering meteorological factors and mission requirements, to fly from takeoff to destination, or to the approach fix serving destination and thence to an alternate airfield, if one is required, plus 10 percent of planned fuel requirements. The fuel reserve at destination or alternate, if required, cannot be less than that required for 20 minutes of flight. If in-flight refueling is planned, sufficient usable fuel must be carried to fly from takeoff point to the Air Refueling Control Point(s) (ARCP), and thence to a suitable recovery field in the event of an unsuccessful refueling attempt. The fuel reserve at rendezvous point cannot be less than 10 percent. For multiple in-flight refuelings, the aircraft must have the required reserve at each rendezvous point. After the last in-flight refueling is completed, the fuel reserve required for the remainder of the flight is the normal requirement as previously discussed. Any known or expected traffic delays must be considered when computing fuel reserves.
5. Pilot in command holds a valid instrument card if applicable.
6. Check for improper filing into an ADIZ, warning or restricted area, or positive controlled airspace.
7. Alternate airport, if required. An alternate airport is required except for VFR flights or for IFR flights when the weather at the destination is forecast to be equal to or better than 3,000 feet ceiling and 3 miles visibility during the period 1 hour before until 1 hour after the ETA.
8. Insure that the weather briefing has been conducted and that the flight is not in violation of established weather minimums for the type of flight.
9. Insure that stopover procedure is understood by the pilot in command, if applicable.
10. Check for the proper weight and balance forms, if applicable. Generally speaking and for weight and balance control purposes, Nav-Air Instruction 13060.2 (Series) classifies the majority of attack, fighter, and trainer aircraft as class 1A or 1B. The majority of cargo and patrol aircraft are class 2. With the exception of aircraft to be ferried, the responsibility for insuring safe loading of class 1A and 1B aircraft is assigned to reporting

custodians. The responsibility for safe loading of aircraft to be ferried rests with the activity preparing the aircraft for ferry movement. The pilot in command of a class 2 aircraft certifies by his signature on the DD-175 that the aircraft's weight and center of gravity will be within safe limits at the time of takeoff and remain so for the duration of the flight. Such a pilot will submit a completed weight and balance form (DD-365F) which represents the actual loading of the aircraft with the DD-175 or, by his signature, certify that a completed DD-365F, dated within the previous 3 months and which represents the actual loading of the aircraft, is on file at the aircraft's home base.

Authorized Airfields

Pilots cannot clear for airfields other than those listed in the current DOD FLIP IFR/VFR Supplement unless such flights are necessary for the accomplishment of a mission assigned by higher authority. The pilot is responsible for insuring that facilities, such as type runway, length, and load bearing capacity are adequate for the type aircraft involved.

All jet aircraft operating in the continental U. S. and engaged in training or itinerant flight are prohibited from landing at or taking off from civil airports, except for those aircraft of units occupying facilities at the airport. Civil airports are those listed in the FLIP Supplements under Directory of Aerodrome as P, FAA, and those airports where the military designation is enclosed in parentheses. Exceptions to this restriction are as follows:

1. Civil airfields on which naval air stations or units of another military service which operate jet aircraft are located.
2. Flights requiring an alternate may use civil airports as alternates when military alternates are not available.
3. When necessary to visit for official business in the area. Written orders are not required.
4. Required flights for procurement, acceptance, modification, test, and delivery of aircraft. This includes ferry flights to permit flexibility in accomplishing the mission.
5. Flights necessary for the accomplishment of unit mission where prior coordination has been effected with the airport authorities involved and where the Type Commander has granted waivers to permit use of the airport involved.

NOTE: These restrictions do not preclude the use of civil airports for the accomplishment of essential approach and low approach training which cannot be accomplished at military airfields.

Helicopters are authorized to land at nonairfield locations such as fields, highways, and parks, with the following provisions:

1. A military requirement exists for such landings.
2. Adequate safeguards are taken to permit safe landing and takeoff operations without hazard to people or property.
3. There are no legal objections to landing at such nonairfield sites.

The above restrictions may be waived by commanding officers when helicopters are dispatched or engaged in rescue operations.

Meteorological and
Communication Services

The clearance authority must assure that provisions for satisfactory meteorological services and air/ground and point-to-point communication services are available, to insure safe and positive flight guard, prior to granting clearance. At those activities where weathervision is installed, the provision of satisfactory meteorological service may be accomplished by this means, provided that the following conditions are met:

1. The weathervision briefing is recorded at the transmitting end.
2. The pilot accepts responsibility for completion of the weather form and gives his name and grade to the weather briefing officer providing the briefing.

Flight Jeopardy

The commanding officer of a naval air activity is not authorized to permit naval aircraft departures from the activity under his command when the state of the weather or the condition of the crew or aircraft is such that, in his estimation, it will jeopardize the proposed flight. This restriction does not apply to cases where Commander Fleet Air Detachment, or a pilot holding a valid special

10764

instrument rating flying as pilot in command, or as flight leader of a formation of aircraft, has authorized flight clearance for a flight.

Non-Naval Aircraft

Aircraft of other military services and Military Airlift Command aircraft are granted clearance in accordance with their respective instructions. Civil aircraft will be cleared in accordance with FAA regulations.

VFR FLIGHT CLEARANCE REQUIREMENTS

CLEARANCE APPROVAL

The clearance authority must ascertain that the VFR clearance requested is in accordance with the VFR requirements of FAR 91, other governing regulations, and OpNav 3710.7 (Series).

WEATHER MINIMUMS

Within airspace where FAR 91 is applicable, the cloud clearance and visibility minimums contained therein (illustrated in NavPers 10367-D, AC 3 & 2, chapter 9) prevail throughout a naval VFR flight. If more stringent minimums have been established for the point of departure or destination, as noted in the aerodrome remarks section of the DOD FLIP (En route) IFR Supplement, then the ceiling and visibility must be at or above these minimums in the applicable control zone.

Existing and forecast weather must be such as to permit VFR operations for the duration of the flight. Destination weather must be at least 1,000 feet ceiling and 3 miles visibility, or such higher minimums as noted in the aerodrome remarks section of the DOD FLIP (En Route) IFR Supplement, and forecast to remain at or above these minimums during the period from 1 hour before until 1 hour after ETA.

Exceptions to the preceding paragraph are as follows:

1. Deviations pursuant to FAR 91.107, Special VFR Weather Minimums, are permitted subject to an ATC clearance.

2. Outside of controlled airspace, helicopters may be operated below 1,200 feet above the surface when the visibility is less than 1 mile, if operated at a speed that allows the pilot adequate opportunity to see and avoid other air traffic and maintain obstacle clearance.

Where FAR 91 is not applicable, FLIP Planning Section III, International Flight Rules and Procedures, outlines the general flight rules for operation of military aircraft in such airspace.

Aircraft must be instrument equipped and pilots must be qualified for instrument flight to fly VFR above a ceiling.

Fixed wing aircraft must maintain at least 500 feet above the terrain or surface of the water except when landing or taking off or when the mission of the flight requires otherwise.

Prior approval must be obtained for a simulated instrument approach from the appropriate approach control facility or from the control tower at locations not served by an approach control facility. At an airport with no tower, the associated FSS, if applicable, must be notified.

IFR FLIGHT CLEARANCE REQUIREMENTS

In order to decrease the probability of midair collisions, all Navy/Marine Corps point-to-point and round-robin flights within the conterminous U.S. should, to the maximum extent practicable, be conducted in accordance with IFR procedure. This procedure is not always practicable and pilots should not be required to adhere to it when one or more of the following conditions exist:

1. When compliance would result in derogation of the mission or task.
2. When necessary to avoid severe weather.
3. When dictated by an in-flight emergency.

Pilots of point-to-point helicopter flights should be encouraged to file IFR where feasible and when the aircraft is suitably equipped.

An IFR or combination VFR/IFR flight plan must be filed for all flights of naval aircraft which may reasonably expect to encounter in-flight IFR weather conditions during any portion of the planned route. The VFR portion of the flight must meet the VFR criteria at

10765

the time of departure and be forecast to remain so during that period.

CLEARANCE APPROVAL

The clearance authority must ascertain that the clearance requested is in accordance with the IFR requirements of FAR 91, OpNav 3710.7 (Series), and other governing regulations.

WEATHER

IFR clearance is based on the actual weather at the point of departure at the time of clearance and forecast weather en route, at destination, and at destination alternate during the period 1 hour before until 1 hour after ETA. Existing weather may be used as a basis for clearance when no forecast weather is available and the pilot's analysis of available data indicates satisfactory conditions for the planned route. Clearance cannot be authorized for destinations at which the weather is forecast to be below minimums (depicted in table 2-1) upon arrival, except when one of the following conditions exists:

1. The flight clearance is authorized by a Commander Fleet Air Detachment.
2. An alternate airport is available which is forecast to be equal to or better than 3,000 feet ceiling and 3 miles visibility during the period 1 hour before until 1 hour after ETA at the alternate.

Flights should be planned to circumvent areas of forecast atmospheric icing conditions and thunderstorms when practicable.

Severe Weather Forecast (WW)

Clearance authorities or pilots who possess clearance authority should not authorize flights through areas for which an Aviation Severe Weather Forecast (WW) has been issued unless the aircraft performance characteristics permit an en route flight level above existing or developing severe storms, or storm development has not progressed as forecast for the planned route. In the latter case, the following conditions apply:

1. VFR clearance may be authorized if existing and forecast weather for the planned route permits such clearance.
2. IFR clearance may be authorized if the aircraft has radar installed, thus permitting detection and avoidance of isolated thunderstorms.
3. IFR clearance may be authorized in positive control areas if visual meteorological conditions can be maintained thus enabling pilots to detect and avoid isolated thunderstorms.

Exceptions to the above restrictions are flights of operational necessity, emergencies, and flights involving all-weather research projects or weather reconnaissance.

INSTRUMENT FLIGHT RULES

IFR flights of naval aircraft are governed by the rules and procedure in FAR 91. The following conditions are in addition to those established therein.

IFR ALTITUDES

Except when the mission of the flight requires otherwise, naval aircraft operated IFR outside of controlled airspace must maintain at least 1,000 feet above the highest terrain, surface of the water, or obstacle within 25 miles of the intended line of flight. When operated IFR outside of controlled airspace, over designated mountainous terrain as shown in the appropriate DOD FLIP, a naval aircraft must maintain at least 2,000 feet above the highest terrain or obstacle within 25 miles of the intended line of flight.

Naval aircraft operated IFR within controlled airspace cannot be flown at less than the minimum en route altitude or that altitude specified by the agency exercising control over the area concerned.

INSTRUMENT DEPARTURES

If a departure takes place under IFR conditions, takeoff weather minimums must be considered. In addition, an approved standard instrument departure may be applicable.

Takeoff Minimums

No takeoff weather minimums apply to pilots who hold a valid special instrument rating.

10766

is also used as a phase reference for the amplitude difference signals which are the elevation and traverse error signals. The sum signal is obtained in the following manner. The energy from horns A and B is applied to the ring HY-2. These signals are 180° out of phase with each other. (Remember that the waveguides are different between these two horns and the ring.) Now, according to rule 4: the output of the Σ arm will be proportional to the sum of the amplitudes of the input signals, (A + B). The energy from horns C and D is applied to the ring HY-3. The action here is the same as for ring HY-2. The output of the Σ arm of HY-3 is C + D. The signals A + B and C + D are 180° out of phase with each other and are applied to the ring HY-1. The output of the Σ arm of HY-1 is the sum of both signals or (A + B) + (C + D). This signal is sent to the radar receiver.

The traverse difference signal is made up of signals from horns A and C added in phase, and from horns B and D added in phase, but the latter combination of energy is 180° out of phase with the energy from A and C. The energy from horns A and B enters ring HY-2 and, in accordance with rule 4, the output from the Δ arm is the difference of the input signals. This signal A - B is sent to HY-4. The energy from horns C and D enters ring HY-3. The output from the Δ arm of the ring is C - D, which is sent to HY-4. The output of the difference arm of HY-4 is the difference between the two signals, which can be stated as (A + C) - (B + D). Note that this statement determines the difference in energy received from the left-hand horns, A and C, and from the right-hand horns, B and D. This signal is then sent to the traverse mixer in the receiver.

The elevation difference signal consists of the signals from horns C and D added 180° out of phase with A and B signals: (A + B) - (C + D). This signal is arrived at by using the Σ arm of HY-2 and HY-3, and the Δ arm of HY-1. Note that this signal compares the energy received in the upper horns A and B with that received in the lower horns C and D. The signal is sent to the elevation mixer in the receiver.

The elevation and traverse difference signals are compared in the radar receiver with the sum or reference signal. The output of the receiver may be positive or negative pulses, the amplitude of which is proportional to the displacement of the target from the boresight (beam) axis. The polarity of the output pulses indicates the direction of the displacement. NOTE: The positive or negative output of the receiver is determined by the phase relationship of the ranging signal and the error signal. An example of how this phase difference may be detected can be found by a review of the magic-T coupler in chapter 11 of this course. Of course if there is no angle tracking error, the output is zero.

This monopulse system provides direct amplitude comparison of the RF signals. Hence noise generated by the local oscillator and produced in the IF section of the receiver has less effect on the angle tracking system.

SYSTEM ERRORS

In any of the monopulse antenna systems, pointing errors can arise in two distinct ways. Phase or amplitude discrepancies in the received signals, which result from asymmetries in the feed structure from radome refraction, give rise to pointing errors. A second contribution to the pointing error arises from the combined effects of the radome error and the asymmetries and phase errors between the parallel receiver channels which are required in a monopulse system. Signal errors in phase or amplitude are always present to some degree, since the feed structure and the radome cannot be perfect. Similarly, phase discrepancies between receiver channels will generally be present. For satisfactory system performance, however, it is mandatory that both sources of pointing error be minimized; in fact, the design of IF amplifiers with satisfactory phase characteristics over a large dynamic range constitutes one of the major problems in a monopulse system.

A constant phase distortion causes the antenna pointing angle to deviate a fixed distance as long as the frequency is constant; however, at a constant frequency, variations will occur in the errors introduced by amplitude distortions in combination with phase errors between receiver channels.

Some shift in itself is not detrimental (as long as the frequency is constant), since it merely defines a new pointing axis. The position of the new axis, however, varies with frequency, and it is the shift of the pointing axis with frequency which is important. The phase error between feeds may result from

1074 4501

Takeoff depends on the judgment of the pilot and urgency of the flight.

For pilots who hold a valid standard instrument rating a takeoff minimum of 300 feet ceiling and 1 mile visibility applies. When a radar approach facility with published minimums less than 300 and 1 is available, takeoff may be authorized, provided the weather is at least equal to the precision approach (PAR) minimums for the runway in use but in no case when the weather is less than 200 feet ceiling and one-half mile visibility.

Two-aircraft formation takeoffs for subsequent flight into IFR weather conditions may be authorized, provided the weather is at or above the published circling minimums for the runway/airport in use. In the event a circling approach is not authorized, VFR weather minimums apply.

If available, runway visibility may be used to determine the visibility appropriate to a particular takeoff minimum.

Standard Instrument Departure (SID)

Where available, the use of approved SID's is encouraged for IFR departures. An appropriate SID procedure should be suggested to pilots during preflight planning in order for them to realize the greatest benefit from standardization of instrument departures.

INSTRUMENT APPROACHES AND LANDING MINIMUMS

Approved instrument approach procedures are published in DOD Flight Information Publications (Terminal) or other similar type publications. Landing minimums for precision and surveillance radar approaches are published in DOD Flight Information Publication (IFR Supplement). If available, runway visibility may be used to determine the visibility minimums except that prevailing visibility is used for circling approaches.

Definitions

For the purpose of instrument approach criteria, the Navy defines multipiloted and single-piloted aircraft as stated in the following paragraphs.

SINGLE-PILOTED AIRCRAFT.—A single-piloted aircraft is any aircraft that has one set of flight controls or any aircraft configured with two sets of flight controls and being operated by only one pilot, except that tandem cockpit aircraft are considered as single-pilot aircraft regardless of the number of pilots embarked.

MULTIPILOTED AIRCRAFT.—A multipiloted aircraft is any aircraft that has two sets of flight controls located side by side in a single cockpit and operated by two pilots. Single-piloted aircraft with side by side seating occupied by the pilot in command and an assisting crewmember, which are configured for and assigned all-weather missions, may operate within the same clearance and approach criteria assigned to multipiloted aircraft provided the assisting crewmember has the equivalent of an instrument rating (in accordance with chapter 10, OpNav 3710.7 (Series)) in type aircraft and can monitor the pilot's flight instruments, monitor and control communications, and assist the pilot in acquiring the runway visually.

Approach Criteria

SINGLE-PILOTED AIRCRAFT.—An instrument approach is not commenced in single-piloted aircraft when the reported weather is below the minimums prescribed in table 2-1 for the type approach being conducted, unless an emergency exists. However, once an approach has been commenced, a pilot may, at his discretion, continue the approach to the approved published landing minimums as shown in the appropriate Flight Information Publication for the type approach being conducted.

The absolute minimums for a single-piloted aircraft on a precision approach are: 200 foot ceiling/height above touchdown (HAT) and visibility one-half mile/2,400 feet RVR or published minimums, whichever is higher.

AIRCRAFT IN FORMATION.—Formation flights of more than two aircraft during descent in instrument weather conditions are prohibited except in an emergency.

Formation flights may not commence an instrument approach when the reported weather

10767

is less than circling minimums for the runway/airport in use unless an emergency exists.

In the event a circling approach is not authorized, VFR weather minimums apply. Once an approach has been commenced, the leader may, at his discretion, continue the approach in formation to the approved landing minimums as shown in the appropriate FLIP for the type of approach being conducted.

MULTIPILOTED AIRCRAFT, RECIPROCATING AND TURBOPROP.—Except in an emergency, instrument approaches in reciprocating and turboprop multipiloted type aircraft may not be commenced when the reported weather is below approved published landing minimums unless it has been determined that the aircraft has the capability to proceed to an alternate airport in the event a missed approach must be executed.

MULTIPILOTED AIRCRAFT, JET.—Except in an emergency, jet multipiloted aircraft may not commence an approach when the reported weather is below the approved published landing minimums for the type approach being conducted. Once an approach has been commenced, a pilot may, at his discretion, continue the approach to the approved published landing minimums as shown in the appropriate FLIP for the type approach being conducted.

CRITERIA FOR CONTINUING INSTRUMENT APPROACHES TO A LANDING.—The published minimum alitutude, minimum descent altitude, or decision height, as applicable, is the lowest altitude to which any aircraft may descend during an instrument approach, unless the pilot has the runway environment in sight and landing can be executed, either straight-in or from a circling approach, whichever is speicifed in the approach clearance. A missed approach must be immediately executed upon reaching the missed approach point if the runway environment is not in sight or if a safe landing cannot be made. For PAR approaches, the point at which the glide path elevation and minimum altitude or decision height coincide must be used to identify the missed approach point.

FINAL APPROACH ABNORMALITITES DURING RADAR APPROACHES.—The radar controller will issue instructions to execute a missed approach or climb and maintain a specific altitude and fly a specified course, whenever the completion of a safe approach is questionable because one or more of the following conditions exist:

1. Safe limits for the radar approach are exceeded or radical aircraft deviations from the normal approach are observed.
2. Position or identification of the aircraft is in doubt.
3. Radar contact is lost or a malfunctioning radar is suspected.
4. Field conditions, conflicting traffic, or other tower observed unsafe conditions, preclude approach completion.

Execution of the missed approach by the pilot is not always necessary for conditions stated in sentences numbered 1, 2, or 3 in the preceding paragraph if the pilot has the runway or approach/runway lights in sight. In these cases, controller phraseology is: "IF RUNWAY OR APPROACH/RUNWAY LIGHTS NOT IN SIGHT, EXECUTE MISSED APPROACH (reason)." The reason might include loss of radar contact, etc.

Execution of the missed approach is MANDATORY for the condition stated in sentence numbered 4 in a preceding paragraph in this section. Controller phraseology should be "EXECUTE MISSED APPROACH (reason)." The reason might be traffic on the runway, etc. The controller may issue instructions to climb and maintain a specific altitude and fly a specified heading, giving the reason therefore, instead of the applicable missed approach procedure.

Practice Approaches

These criteria are not intended to preclude single aircraft from executing practice approaches (no landing intended) at a facility when operating in conformance with an appropriate clearance and the weather at the intended final distination, and alternate if required, meet the criteria for an instrument clearance.

WEATHER CRITERIA FOR IFR CLEARANCES

Table 2-1 shows the actual or forecast weather, as appropriate, to be used as criteria in the approving of clearances for flights to be conducted under instrument flight rules.

10768

Table 2-1.—Weather criteria for IFR clearances.

Destination		Alternate	
VOR, TACAN, ADF, ASR, LF RANGE, LOC.	ILS, PAR, ALS	VOR, TACAN, ADF, ASR, LF RANGE, LOC.	ILS, PAR,** ALS
Published landing minimums	Published landing minimums. *	300 feet ceiling and 1-mile visibility both above published landing minimums; e.g., published minimums are 400 and 1, then weather must be at least 700 and 2.	200 feet ceiling and one-half mile visibility both above landing minimums.

* Single-piloted aircraft: Not less than 200 feet ceiling/HAT and one-half mile visibility (2,400 feet RVR).

** Single-piloted aircraft and those multipiloted aircraft equipped with only one operative means of two-way communications: Not less than published ADF, VOR, TACAN, or LF RANGE minimums as applicable to installed equipment/navaids available.

FLIGHT PLANNING SECTION

In flight planning, pilots utilize the facilities and space provided in the flight planning section of air operations. Here pilots assemble the necessary information, which is required for a proposed flight, on the flight plan log and the aircraft clearance form (DD Form 175).

Flight planning facilities of operations buildings vary in size, depending on the mission of the station and the amount of traffic that they support. Examples of two different missions are major training stations and fleet support stations. The intent is to provide space and facilities sufficient to permit a reasonable number of pilots to concentrate on flight planning problems at the same time without crowding or other unnecessary annoyance during this important phase of every flight.

EQUIPMENT AND LOCATION

The purpose of the flight planning section is to provide a centralized collection of aeronautical information necessary for, and required by, aircrews to prepare flight plans.

The flight planning section should be located, organized, and equipped in conformity with the following standards:

1. It should be located in a convenient position adjacent to the weather office and the clearance desk. Its location should be clearly indicated by direction indicators to guide transient aircrews.
2. It should be manned by Air Controlmen trained and qualified to maintain flight information publications and associated wall displays. The personnel assigned to this section should be in sufficient numbers to operate the section throughout the normal working hours of the air establishment.
3. It should include adequate accommodation with suitable furnishings for aircrews to thoroughly prepare their flight plans in reasonable comfort. The furnishings should include wall space for the display of required aeronautical information, plotting tables, adequate lighting arrangements, and storage for charts, publications, and forms required by aircrews.
4. Navigation equipment must include plotting instruments, flight comupters, and a clock indicating Greenwhich Mean Time.
5. Sufficient quantities of flight information publications and related information applicable to the mission of the activity and area of location should be available.

10769

6. NOTAM's decoded to plain language (if necessary) must be maintained up-to-date for ready reference.

7. The following publications are utilized occasionally for reference purposes and should be available in limited quantities where required:

a. Federal Aviation Regulations, Volume VI.
b. Airman's Information Manual.
c. International NOTAM's (FAA).
d. International Flight Information Manual.
e. Air Almanac.
f. Foreign Clearance Guide.
g. Language Glossaries.

AERONAUTICAL CHARTS AND PUBLICATIONS

One of the flight clearance section supervisor's functions should be to insure that an adequate stock of aeronautical charts and publications is maintained in the flight clearance spaces and that they are kept current and corrected. All the Navy's aeronautical charts and publications are procured and distributed by the Naval Oceanographic Office (NAVOCEANO).

The Oceanographer of the Navy is responsible for production or procurement, inventory management, and distribution of navigational and intelligence material to meet the Navy/Marine Corps operational requirements. He also maintains appropriate liaison with agencies within the Department of Defense, Coast and Geodetic Survey, and other chart producing agencies regarding production procurement, and distribution matters.

The general stocking pattern of the Naval Oceanographic distribution system is as follows:

1. Naval Oceanographic Distribution Offices (NAVOCEANDISTO's), of which there are two: Clearfield, Utah, which supports the Pacific area and the continental U. S. (CONUS) west of the Mississippi river; Philadelphia, Pa., which supports the Atlantic area and CONUS east of the Mississippi River. The NAVOCEANDISTO's serve as primary stock and distribution points.

2. Air Navigation Offices (AIRNAVO's), of which there are three to provide service west of the Mississippi River and four to provide service east of the Mississippi River. Each AIRNAVO has a geographical area of the world for which it is responsible. They stock and issue aeronautical charts and publications, selected periodicals, air intelligence publications, and Army maps. Additionally, selected nautical chart portfolios and related publications are stocked uncorrected for emergency issue.

The requisitioning of aeronautical material from the NAVOCEANO distribution system is accomplished as described in the DOD Catalog of Aeronautical Charts and Publications. The purpose of this catalog is to provide a listing of USN/USAF aeronautical charts and publication, DOD Flight Information Publications (FLIP's), and miscellaneous items available to DOD users. This catalog itself is a looseleaf notebook type publication containing several sections, each of which describes certain procedures or charts and publications available. For example, Section II consists of requisitioning and distribution procedure which must be followed and Section III lists the FLIP's available, etc. The catalog is kept current by semiannual publication of new or replacement pages containing changes or additions. There is also a classified DOD Catalog of Aeronautical Charts and Publications of similar construction for ordering classified charts and publications.

That portion of Section II that applies to Navy/Marine Corps requisitioning procedure should be the subject of the supervisors close attention both in general use and training. This section contains complete information necessary to correctly order needed aeronautical charts and publications, including the source to order from. Figure 2-1 is an example of a completed DD Form 1149, which is the document used for requisitioning charts and publications from the NAVOCEANO distribution system.

In order to expedite the processing of requisitions, items should be double spaced on the DD Form 1149 and separate requisitions should be submitted for each category of material as follows:

1. Charts.
2. Publications.
3. FLIP's.

All requisitions must be signed by the Commanding Officer or his authorized representative.

earof 10770

Figure 2-1.—DD Form 1149.

10771

The spaces to be filled out on the DD Form 1149 are explained in figure 2-1. The following explanation provides additional background information:

1. In block number 6, requisition number, the first portion of the number should be the unit identification code preceded by the letter N. This is referred to as the activity account number in the catalog. Unit identification codes consist of 2, 3, 4, or 5 numeric or alphabetical characters assigned by the Comptroller of the Navy to identify bureaus, systems commands, ships, aircraft units, shore activities, etc. In machine processing the unit identification codes of less than 5 characters would be preceded by zeros to make a five character field. The DOD Activity Address Directory (DODAAD) provides a code designation and clear text address of each DOD activity that requisitions or receives material. The code in the DODAAD for all Navy activities and certain Marine Corps activities consists of the unit identification code assigned by the Comptroller preceded by the letter N or M respectively. The second portion of the requisition number indicates the Julian date, which consists of two elements: the last digit of the calendar year and the numerical consecutive date of the calendar year. In the example in figure 2-1 the year is 1968 and the day is the 182nd consecutive day of the year or 30 June. The numerical consecutive day of the year may be found on government issue calendars.

The unit identification code of each Navy activity can be found in NAVCOMPT Manual, Vol. II, or the DODAAD. If neither of these references is available, the activity Comptroller Department may be contacted by telephone.

The last portion of the serial number is the requisitioning activity's request number. This number on each new requisition must increase by at least one digit. A log may be maintained so that as each requisition is prepared, its originator's serial number is assigned and logged to prevent duplication and/or omissions.

2. Block 7 is normally blank unless the material is required prior to/or after the time allowed by the issue priority designator shown in block 8. In the Uniform Material Movement and Issue Priority System, the issue priority designator is determined by a combination of factors which relate the military importance of the requisitioner (Fleet Activity Designator) and the urgency of need designator. The Fleet Activity Designator (FAD) is a Roman numeral (I to V) and is assigned by appropriate authority within the chain of command. The FAD for any activity may be obtained by contacting the Supply Department of that activity. The urgency of need designator (an alphabetical letter) is determined by the requisitioning activity using the guidance and criteria shown in table 2-2.

With certain exceptions, these two factors (FAD and UND) will enable the requisitioning activity to determine the issue priority designator (IPD). For example, suppose that you are ordering aeronautical charts; you determine that your FAD is IV, and considering your ship's expected deployment date and the necessity of the charts you determine that the urgency of need designator should be C. By referring to table 2-2 you locate FAD IV, then move down the column directly below the IV until adjacent to the urgency of need designator C. This gives you an IPD of 14. This is the number that you would place on the DD Form 1149 in the priority block. The two columns to the extreme right side of table 2-2 titled priority delivery date (PDD) show the time necessary for normal processing and shipping. The PDD is determined by adding the appropriate time allowance from the last two columns in table 2-2 to the date of the requisition, which is the Julian date included as part of the requisition number in block 6. If the requisitioner determines that this PDD will not meet his requirements, then a required delivery date may be assigned. This would be a Julian date entered in block 7 on the DD Form 1149. When the required delivery date is prior to the priority delivery date, then justification must be written on the DD Form 1149 under the description of the charts ordered. If the required delivery date is later than the priority delivery date, then the appropriate Julian date only is entered in block 7. As mentioned earlier, if the PDD will suffice, then block 7 is left blank.

3. The Commanding Officer or his authorized representative must sign the DD Form 1149 and is required to personally review any urgency of need designator A and validate it. Additionally, and urgency of need designator B must be reviewed and validated by persons designated by the Commanding Officer. The supervisor should insure that control of issue priority designator utilization is exercised in

10772

Table 2-2.—Issue priority designators.

URGENCY OF NEED DESIGNATOR (UND)	FORCE/ACTIVITY DESIGNATOR (FAD)					PRIORITY DELIVERY DATE (PDD)	
	I	II	III	IV	V	CONUS	OVERSEAS
	ISSUE PRIORITY DESIGNATOR (IPD)						
DESIGNATOR A							
Emergency requirements for nonavailable material without which the force/activity concerned is unable to perform assigned missions or tasks.	01	02	03			5 days (120 hr)	7 days (168 hr)
				07	08	8 days	15 days
DESIGNATOR B							
Requirements for nonavailable material which impairs the capability of the force/activity concerned. Missions can be performed, but with decreased operational effectiveness and efficiency.	04	05	06			8 days	15 days
				09	10	20 days	45 days
DESIGNATOR C							
Material requirements needed on a more urgent basis than routine. For example, immediate end use requirements for repair of collateral and administrative support equipment; to meet scheduled deployment; or deficiencies in newly established outfitting or allowance lists.	11	12	13	14	15	20 days	45 days
DESIGNATOR D							
Material requirements for initial outfitting and filling of allowances, scheduled maintenance, routine stock replenishment, repair or maintenance of supply systems stocks.	16	17	18	19	20	30 days	60 days

10773

the division and kept realistic before submitting the requisition for an approving signature.

4. FLIP's are distributed in predetermined quantities and to a predetermined list of addresses or automatic distribution. The basis of distribution is in accordance with a table included in Section III of the Catalog of Aeronautical Charts and Publications. When requisitioning FLIP's using the DD Form 1149, if automatic distribution of subsequent issues of the material ordered is not required, then a statement that the request is a one-time request must be included on the form. An annual survey is made by NAVOCEANO to establish, confirm, or revise organizational requirements for FLIP's to keep the automatic distribution effective.

Chart Updating Information

Additional updating information on aeronautical charts is provided for DOD users listed in the catalog in two monthly publications. The DOD Aeronautical Chart Updating Manual (CHUM) is published to furnish information on significant chart changes and corrections. Each monthly CHUM supersedes the previous one. The DOD Aeronautical Chart Bulletin is published to inform users of new editions of charts and publications, to furnish information on replacement charts, and to provide notices pertaining to supply. Semiannually a DOD Aeronautical Chart Bulletin Digest is published to list the current edition dates of all charts shown graphically in the catalog. The monthly bulletin is a cumulative system which contains new additions since the last bulletin was published and they should be retained for the six month period preceding publication of the Bulletin Digest. The Bulletin Digest includes the still new or revised information from those previous six bulletins and when the Bulletin Digest is received, the previous six bulletins may be discarded and the process starts again.

To determine if a chart is a current edition, use the following procedure:

1. Check the edition number of the chart against the edition number listed in the latest Bulletin Digest and subsequent monthly bulletins. If the numbers are the same, the chart is current. If the bulletins list a higher edition number, the chart is obsolete and should be replaced.

2. Check the CHUM to see if the chart requires modification. Refer to Section II of the latest CHUM for a listing of charts which require additional or updating information. If the chart is listed, refer to Section III of the CHUM for the correction information and apply the changes to the chart.

3. Check Section IV of the CHUM to see if there are any special notices that contain corrective information for the chart.

4. Check NOTAM files and Memorandum for Aviators files for possible navigation notices which may effect the chart.

There is also a classified DOD CHUM of similar construction for use with classified charts.

WALL DISPLAYS

Certain types of information required to be available in flight clearance can be displayed very effectively as a wall display. The amount, extent, and complexity of such displays are dictated by the mission of the particular activity. However, the following items of information are examples of material which may be made available in flight clearance as wall displays:

1. A general flight planning chart. This chart should be a large one such as the FLIP low altitude planning chart, and have some means of measurement for roughly determining distance of considerable magnitude, for preliminary planning.

2. A local flight planning chart(s) of suitable scale showing VFR ingress and egress corridors.

3. Scaled terrain/obstruction charts which may include overlays depicting current SID courses and their proximity to known hazards.

4. Charts showing details of local special use airspace and training areas, including limits of the local flying area.

5. A wallboard, appropriately marked, upon which to place effective Memoranda for Aviators.

6. NOTAM display. A standardized display board for NOTAM's as prescribed in OpNav 3710.7 (Series) is designed to accommodate the publication procedure of the Navy/Air Force NOTAM system. This particular area of responsibility of the flight clearance supervisor

10774

should receive considerable attention. He must insure availability of sufficiently knowledgeable personnel to maintain a current NOTAM display and to assist pilots in checking the NOTAM information. The NOTAM board must be constantly updated, at least once each hour, and obsolete material must be promptly removed. When a new NOTAM is received, the Summary should be updated immediately. The accuracy of NOTAM's for your particular activity should be verified at least one hour after receipt of the Summary. Since the sole purpose of the NOTAM system is to assist the pilot in safer flight and the information is only of value after it reaches the pilot who is planning a flight, the effectiveness of the entire NOTAM system depends on how well each individual performs the functions assigned.

7. Lighted or other types of display boards to indicate general flying weather conditions are not mandatory. If used, however, such displays must be standardized to show terminal ceiling and visibility conditions indicated by the following color codes:

a. At or better than ceiling and visibility minimum prescribed for flight under VFR.—GREEN.

b. Below ceiling and visibility prescribed for flight under VFR but at or above the lowest minimum for an approved instrument approach, including PAR.—AMBER.

c. Below the lowest minimum for an approved instrument approach, including PAR.—RED.

USE OF FLIGHT CLEARANCE EQUIPMENT AND SAFETY PRECAUTIONS

Most Flight Clearance officers have some type of landline (direct phoneline) equipment for direct voice communications with ARTCC, FSS, etc. All such phone lines are identified by a particular number. Correct procedure to follow if these lines should fail is developed locally by the supervisor. Supervisors must insure that all personnel in Flight Clearance are familiar with such procedures. It is especially important that they know what to do and who to call on the regular telephone in case of a direct line failure.

Teletype machines in Flight Clearance will probably require more attention from a supervisor than most other equipment since they are relatively difficult to operate correctly. The supervisor must insure that the operators are properly indoctrinated concerning the proper codes prescribed for the particular types of messages that his office sends. This is especially important with automatic systems since improper coding of a heading to a message may cause the message to be rejected by the computer that routes the message to intended receivers. This would require doing the same job again, which introduces a delay in message delivery. Normally there is a time lapse of at least 30 minutes between the time the pilot of a proposed IFR flight submits his proposed flight plan until he calls departure control for his clearance. If too many delays are introduced into the processing and submission of the proposal via teletype, the clearance may not be available when the pilot is ready for it. Considering the expense of the aircraft and pilot sitting there waiting for clearance, when the delay problem is at the Flight Clearance office, the necessity for correct and rapid communications should be apparent.

As in any situation, the senior personnel of Flight Clearance must be continuously safety conscious. They should make periodic inspections of work areas of Flight Clearance for potentially hazardous situations. Around teletype machines, consider the following precautions or actions:

1. The top cover of the machine should never be opened when anyone is working around it with metal objects such as paperclips, thumb tacks, etc., that might fall into the mechanism. Such objects, if allowed to fall into the machine, could severly damage it or possibly short out an electrical component and cause an electrical fire.

2. If an electrical fire should result, unplug the machine or otherwise disconnect the electrical circuit, such as with a master switch. It may be necessary to use a fire extinguisher. Be sure a CO_2 extinguisher is available in the area and that everyone knows the location.

3. Insure that personnel are properly indoctrinated as to the proper procedure for replacing teletype paper and ribbons since improper installations may jam or damage the machine or in any event delay its return to service.

10775 ATTOI

FLIGHT CLEARANCE SUPERVISOR

The supervisor is the key to the efficient and effective function of any operation. Flight Clearance may be considered one of the most important functions of the ATC division. Although it does not include what may be considered the more exciting functions of actually controlling air traffic, as do the tower or RATCC, it probably presents the greatest challenge to a supervisor. It is at Flight Clearance that physical contact is made between the users of, and the air controlmen who provide, air traffic control services. Logically, the image or personality of the division, department, and station may be the result of the majority of opinions formed concerning the services received, culminated by this contact.

It is a generally accepted practice to assign the young personnel, new to the Navy, to Flight Clearance to begin their development of air traffic control skills. These men have a tendency to try to imitate or take for their own those qualities they admire and respect in those they identify as leaders. If the leaders they respect and admire are skillful, aggressive, and professional air controlmen who create by their interest and action a good attitude toward flight clearance functions, then these new men will develop good attitudes. A supervisor wants his men to be cooperative, to be willing to pitch in when emergencies arise, to have pride in the organization, and to feel they have a stake in it. These cooperative attitudes are a byproduct of a supervisor's dealings with his men.

A supervisor can stimulate interest in flight clearance by helping his men see why their work is needed and how it fits into the whole pattern of air traffic control. He can develop their initiative by encouraging them to join in figuring out ways of making their work easier and better, and by delegating jobs to those who can and should be doing them and occasionally checking and acknowledging the fact that they are done properly. At the same time the supervisor must avoid stifling initiative by oversupervision.

A supervisor will necessarily carry out an orientation program for all new men. But it takes more time and attention to get the younger men off to a good start. This is worth doing because they have many useful years in the Navy ahead of them if they get started right. The new men probably lack confidence and it is up to the supervisor to relieve the tension. Once they have some confidence, are familiar with their surroundings, know their shipmates, and know who is to give them orders, they are able to learn faster. It may be helpful to put them under the wing of a more experienced air controlman to help them adjust and find their way around.

The flight clearance supervisor's professional qualities are already proven by his attained rate and selection to a supervisor position by his seniors. This combined with good training and management practices will insure the efficient and effective operation of the Flight Clearance Branch.

10776

structural asymmetries in the feed, or it can result from radome effects as well. Since the phase errors caused by the radome vary as the antenna scans, a variable shift in pointing axis then results, even with a fixed frequency. The major source of error for both phase and amplitude comparison monopulse systems are in the feed system as follows:

1. For the phase comparison system the primary errors are phase errors, and secondary errors are amplitude errors (in front of the sum and difference circuits).
2. In the amplitude comparison systems the primary errors are amplitude errors and secondary errors are phase errors.
3. Both systems experience phase errors between receiver channels.

PULSE EXPANSION AND COMPRESSION

Within the past few years, an amazing and powerful radar technique called pulse compression (nicknamed "Chirp Radar") has been incorporated in all types of radars. Pulse compression is possibly the most significant new advance in radar techniques in many years. It can improve a radar's performance by a factor of possibly several hundred. There appears to be no limit in sight to its possibilities. It is finding use in long range search, missile control, fire control, weather observation, aircraft traffic control, and mapping radar, and many more. Frequently, computers are used to display the returned target information using standard target symbols rather than displaying conventional video on a PPI type indicator. These symbols depict target position, size, type aircraft, and movement of the target. Generally, the radar is computer controlled.

ADVANTAGES

Some of the advantages which are discussed in this section are extended range with improved range resolution, height finding capabilities, immunity from ECM jamming, and an increased signal-to-noise ratio.

Extended Ranges

One important factor in any radar's maximum range is the envelope power. Envelope power is found by multiplying the pulse width times the peak power. The AN/APS-20, which is a typical search radar, has a pulse width of 2 μsec and a peak power of 2.5 megawatts. This will produce an envelope power of 5 watts/sec. A typical pulse compression radar will have a pulse width of 10 μsec and peak power of 1 megawatt which will produce an envelope power of 10 watts/sec. Since range is partially determined by the transmitter, this will give us the possibility of an increased range over the conventional pulse radar.

Improved Range Resolution

Range resolution is the minimum distance which two targets must be separated to appear as two separate displays on a scope. This separation is largely determined by the pulse width of the echo being returned to the receiver. In our typical conventional radar with a 2-μsec pulse width, range resolution would be 1,000 feet. In the pulse compression radar, the 10-μsec returned pulse is compressed to 0.1-μsec before being applied to the receiver. Therefore, the range resolution is 0.1 x 500 or 50 feet. This improved range resolution is accomplished without affecting maximum range because the envelope power is not changed.

Height Finding Capabilities

The theory employed by pulse compression to determine height is based on the ability of the radar to receive multiple path returns from a single target. With sufficient power, receiver sensitivity, and range resolution, the system can distinguish between three echo returns. (See fig. 15-14.) By measuring the time difference of the three returns and comparing the altitude of the radar transmitter, the computer can determine the target altitude. Only the pulse compression radar has both the

Figure 15-14.—Multiple echo paths.

1075

CHAPTER 3

FACILITY OPERATION

Because of the many advantages of standardization, the Navy has endeavored to apply this principle to air traffic control to the extent possible. Cooperation with the FAA and other military agencies of the DOD to develop a common civil/military system is one example. The NATOPS program is another. These standards attempt to provide uniform systems of efficient operation and operational guidance for ATC facilities. Differences between agencies and facilities are recognized, however, and appropriate options to provide the required flexibility is retained. It is the intent of this chapter to discuss those procedures applicable to most naval ATC facilities relative to the operation of the facility which are not included or referred to elsewhere in this training course.

AIR OPERATIONS MANUAL

Local flying rules and instructions are found in regulations issued by the various fleets, forces, naval air stations, and other naval activities where aircraft are based or operated. In accordance with OpNav 3710.7 (Series), Navy and Marine Corps facilities develop and publish Air Operations Manuals which should include all those subjects that are considered as local administrative or operational procedure. Since this manual establishes local regulations, it is considered as a continuation or supplement to OpNav 3710.7 (Series) which contains the overall standardized general flight and operating instructions for Navy and Marine Corps facilities.

Senior AC's should become involved with their Air Operations Manual. They should make their ideas for improved or more efficient procedures known to the proper individual in the chain of command. The best possible evaluation of such a publication must come from pilots using and the controllers providing the service regulated by this manual.

The following basic outline for an Air Operations Manual should be adhered to as closely as possible considering local conditions and services offered, which could necessitate some variation.

1. General.
   a. General prudential rules.
   b. Hangar and service facilities (including wheel load capacity of runways and parking aprons).
   c. Night lighting facilities.
   d. Hours of operation.
2. Clearance of aircraft.
   a. Instructions for filing flight plans.
   b. Weather minimums.
3. Course rules.
   a. Taxi instructions.
   b. Takeoff instructions.
   c. Landing instructions
   d. Runway use procedure.
   e. Definition of local flying area.
   f. Acrobatic areas.
   g. Bombing areas.
   h. Local obstructions.
4. Air traffic control.
   a. PAR procedures, if applicable.
   b. Procedures for checking "wheels down and locked."
   c. Emergency procedures.
   d. Procedures for civil operations which infringe upon the control zone and/or airport traffic area, such as crop dusting, sign towing, forest fire fighting, etc.
5. Transient aircraft.
   a. Accomodations available.
   b. Transportation available.
   c. Instrctions for clearance of passengers for flights.
   d. Procedures for handling visiting VIP's.

10777

e. Procedures for expeditiously handling the orders of personnel authorized per diem.

f. Customs procedures, hours, and requirements (at stations on foreign soil and where applicable in the U.S.).

g. Procedures for obtaining flight rations.

h. Procedures for obtaining special aircraft security.

i. Procedures for obtaining required registered publications necessary for flight.

j. Procedures and facilities for temporary stowage of registered material and weapons.

k. Availability of clothing, shaving articles, etc., for unexpected RON's and Bingo crews.

6. Aircraft crash and rescue.
   a. Crash and rescue bill.
   b. Search and rescue bill.
   c. Salvage bill.
7. Illustrations.
   a. Traffic pattern charts.
   b. Taxi pattern charts.
   c. Prohibited, warning, and alert area charts.
   d. Target dropping and bombing area charts.
   e. Scaled terrain/obstruction chart.

One copy of each new or revised Air Operations Manual is sent to CNO, OCEANO, COMNAVAIRSYSCOM and the appropriate NARASPO. Distribution to other activities that use local facilities is accomplished as needed.

A complete and current Air Operations Manual is a definite asset to an ATC facility. By direction, it enjoys faily wide distribution and is useful to interested persons unfamiliar with the local activity who intend to use the facility and services offered. Also, it is a useful tool for a facility's indoctrination and training program since it is a collective publication of regulations which affect local flying operations and procedures.

Moreover, if the Air Operations Manual is ignored and allowed to become a dust catcher in the files, it can be a meaningless waste. The Navy has taken steps to prevent this by requiring, through regulation, that a periodic review be conducted to insure that the subject matter is up to date. However, like any regulation, the effectiveness at the local level depends upon the initiative and insight of those regulated.

FACILITY LICENSE

SecNav Instruction 3770.1 (Series) establishes responsibility and describes the procedures for use of Navy/Marine Corps aviation facilities by other than military aircraft as authorized by the Federal Aviation Act of 1958.

AUTHORITY

The Federal Aviation Act of 1958 states that air navigation facilities owned and operated by the U.S. may be made available for public use under such conditions and to such extent as the head of the department or other agency having jurisdiction thereof deems advisable and may by regulation prescribe.

Navy and Marine Corps aviation facilities are established to support the operation of Navy and Marine Corps aircraft. Equipment, personnel, and material are maintained only at a level necessitated by these requirements. SecNav has established the policy that, except in the case of a bona fide emergency, Navy and Marine Corps aviation facilities will not be used to support the operation or maintenance of commercial or private aircraft except as follows:

1. Aircraft other than those belonging to the U.S. Government may use Navy and Marine Corps facilities if necessary and if so authorized under the provision of SecNav 3770.1 (Series), provided that:
   a. They do not interfere with military requirements, and the security of the military operations, facilities, or equipment is not compromised.
   b. No adequate civil airport is available. (An exception to this is flights in connection with official government business.)
   c. Pilots comply with regulations promulgated by the cognizant military agency and the commanding officer of the facility.
   d. Civil aircraft users assume the risk in accordance with the provisions of the Aviation Facility License.
2. At joint civil/military facilities, the agreement entered into when establishing the joint use operation may take the place of SecNav 3770.1 (Series) concerning civil use.
3. At facilities in foreign countries, the provisions of status of forces agreements,

treaties of mutual cooperation, or other international agreements must also be considered.

4. Aircraft being produced for a military agency under contract may use Navy facilities for testing and experimental purposes if the contract so provides, or it is determined that it is in the best interest of the government to do so.

5. Department of Defense single manager (MAC) contract and charter aircraft may use Navy or Marine Corps facilities when authorized in accordance with a facility license approved by CNO.

CIVIL USE OF NAVAL FACILITIES

The use of naval facilities by civil aircraft is at the risk of the operator. The Navy assumes no liability or responsibility by reason of the condition of the landing area, taxiways, radio or navairds or other equipment, or for notification of such conditions, or by acts of its agents in connection with the granting of the right to use such facility. Additionally, no responsibility is assumed for the security of or damage to aircraft while on government property.

Operators of civil aircraft using a naval facility are required to comply with the air and ground rules promulgated by the Navy or the commanding officer. Such operators are required to comply with FAA requirements for filing flight plans. When a flight plan is required, it must be filed with the commanding officer or his authorized representative prior to departure. When no flight plan is required, the operator must furnish a list of passenger and crewmembers, the airport of first intended landing, the alternate airport, and the amount of fuel in hours to the flight clearance authority, or the local company official, as appropriate, prior to takeoff.

The applicable weather minimums are those established for a specific airline, if appropriate, or those as published in the Airman's Information Manual, or if none are established, those established by the commanding officer.

The commanding officer may conduct an inspection of the aircraft, its crew and cargo, or passengers as may be required. Compliance with local customs, immigration, agriculture, and public health regulations is the responsibility of the aircraft commander. The commanding officer will inform local officials of the arrival of civil aircraft subject to such regulations and will not authorize takeoff clearance until such regulatios have been met.

If a Navy facility has been approved as an alternate airport, radio clearance must be obtained from such facility as soon as the decision is made to use it.

In the case of an emergency landing, the commanding officer will obtain from the pilot of the aircraft a written report of the conditions pertaining to the emergency.

APPLICATION AND APPROVAL OF FACILITY LICENSE

Nonmilitary aviation interests desiring use of a Navy/Marine Corps facility will be required to execute an application (OpNav Form 3770-1) and an Aviation Facility License (OpNav Form 3770-2), and furnish adequate evidence of insurance coverage before approval for use of the facility can be given. The following list contains exceptions to this condition:

1. Aircraft owned or operated by departments or agencies of the U.S. Government.
2. Aircraft owned or operated for noncommercial purposes by agencies of a foreign government, except in the case where the foreign government charges fees for U.S. Government aircraft.
3. Aircraft owned and operated by states, counties, or municipalities of the U.S.
4. Aircraft operated by Navy/Marine Corps flying clubs or Aero Clubs of other military services which are operated as instrumentalities of the Federal Government.

The commanding officer has authority to approve or disapprove operations of civil aircraft at his facility. There are conditions which require higher authority approval, in which case commanding officers forward the application and license to such higher authority.

HANDLING PROCEDURES AT THE ATC DIVISION LEVEL

Copies of approved Facility Licenses are normally on file in the ATC division office for reference. It is necessary that division personnel are aware of the aircraft operators

authorized to use your facility to avoid unnecessary delays when such operations are impending. The simplest procedure would probably be maintenance of a current list of approved licenses in the tower, RATCC, and flight clearance.

EMERGENCY PLANS AND SERVICES

Commanding officers of air facilities are required to develop and maintain current operational plans and procedures to insure maximum protection of aircraft and safety of personnel during an emergency situation. Senior AC's will be called upon for advice and assistance when these plans are developed or updated to insure that they are effective and workable from the air traffic control aspect.

Additionally, training of new personnel in this particular function is probably the most difficult to perform since actual conditions requiring the use of these procedures occur infrequently. Consequently, supervisors must conduct drills frequently which simulate emergency conditions to develop the skills and reactions required of controller personnel.

CRASH AND RESCUE SERVICES

NavAir Instruction 11320.4 (Series) provides the basic policy and organization for performing the crash and rescue function at Navy and Marine Corps air activities. This instruction is the basic document from which commanding officers promulgate the local crash and rescue bill which should be a part of the facility's Air Operations Manual.

The AC's participation in crash and rescue procedure is mainly one of communication; i.e., notification of impending flight operations to permit positioning of equipment in an alert status and notification of a crash or an impending emergency landing to the appropriate stations on the crash alarm system.

At all times when the runways are in use at a facility, a runway alert will be maintained. The runway alert consists of the appropriate men and equipment strategically located to permit the men to observe the entire runway and respond immediately to an emergency. The purpose of the runway alert is rescue of personnel involved in unannounced emergencies and to observe and report any suspected malfunction of aircraft to the control tower. In the event landings and takeoffs are being conducted simultaneously and both operations cannot be observed from one position, a second runway alert should be provided.

At all times when flight operations are being conducted, a standby alert of the appropriate men and equipment should be maintained in a state of readiness such that they can respond to an emergency from their standby position to the field alert position within 3 minutes. The purpose of the standby alert is to supplement the runway alert and provide additional firefighting capability when necessary.

Additionally, a backup standby alert is maintained when flight operations are being conducted consisting of the appropriate men and equipment from the security forces, ordnance disposal crews, and the station firefighting organization in a state of readiness such that they can respond to an emergency promptly from their normal working spaces. These supporting forces should assume the position of standby alert upon notification of an emergency and await the instructions of the senior firefighter at the scene.

AC's in the tower will usually observe or receive information regarding impending emergencies and will notify the crash and rescue crews and other appropriate personnel on the crash alarm system. If such information is initially received at locations other than the tower, personnel in the tower should be notified immediately to permit timely notification to all concerned. Various systems of notification and communications are required for crash and rescue operations at air facilities; these are discussed in detail in AC 3 & 2, NavPers 10367-D.

Crash Drills

Response time seems to be the most important factor to surface when evaluating a reaction to an aircraft emergency other than actual control procedure employed by the air traffic controller. Data on survivable aircraft accidents and fire tests emphasize the urgency of arriving at the accident scene in the shortest possible time. Test and experience data show that occupant escape time can be extended by prompt fire suppression operations. Many items that affect response time are fixed, such as

number and type of crash equipment necessary per category of aircraft operation and the number of personnel necessary to adequately man such equipment. However, crew reaction time is one item which may be considered variable and is affected by communications procedures and practices for the alert. The AC has a definite degree of control of the alert. To enhance development of a minimum response time, frequent drills should be conducted to allow tower personnel to actually use the procedure for alerting the crash crew. The following items should be stressed in each drill:

1. Use of the grid maps to pinpoint accident scenes both on and off the airport.
2. Prompt transmission of messages pertaining to a crash and other information available to assist in the location of the accident scene.
3. Prepositioning of crash equipment when the situation permits advance notice that an emergency exists but the aircraft concerned is still en route to the air station. Although the physical positioning is the Crash Captain's responsibility, the tower controller must concern himself with which runway the emergency aircraft will use, the control of other traffic at the air station, both ground and air traffic, and insuring that such other traffic does not hinder the movement of emergency vehicles and equipment.
4. Tower crew efficiency in effecting an alert when word is received from another source that an emergency situation exists or a crash has occurred.

HAZARDOUS CARGO

The crash and rescue bill must contain provisions for notification of the necessary personnel concerning the movement of hazardous cargo. The operations duty officer and the tower will be aware of the movement by aircraft by inclusion of such information in the normal exchange of flight plan information. Particular phraseology and d scriptive terms associated with hazardous cargo are contained in Navy SWOP 20-11 entitled Precautionary Measures Involving Aircraft Carrying Hazardous Cargo, and are classified Confidential. Senior AC's must make sure that their men have the necessary security clearance and know and understand these terms.

In the event an aircraft carrying hazardous cargo is involved in an emergency, specific information, in addition to the normal emergency procedure, must be relayed to the crash and rescue crews and explosive ordnance disposal personnel for the protection of all concerned. Specific local directives are established for notification procedure of an accident involving special weapons based on OpNav Instruction 8110.16 (Series) entitled Nuclear Activities and Nuclear Weapons Incidents.

SCATANA

A plan for the Security Control of Air Traffic and Air Navigation Aids (SCATANA) was prepared jointly by the Department of Defense, the Federal Aviation Administration, and the Federal Communications Commission. The purpose is to establish responsibilities and procedures to provide for the security control of civil and military air traffic and certain Federal and non-Federal air navigation aids during a Defense Emergency/Air Defense Emergency. SCATANA is disseminated in the Navy as OpNav Instruction 3722.30 (Series).

The North American Air Defense Command (NORAD), based on the requirements of the existing military situation, directs the extent of security control of air traffic and air navigation aids in the area or areas affected in the interest of national security. Full SCATANA procedures may be implemented or, in limited situations, only the Emergency Security Control of Air Traffic (SCAT) rules may be placed in effect. Emergency SCAT rules are contained in FAR 99 and provide for the ready identification and control of all air traffic in the event of a Defense Emergency.

Upon declaration of an Air Defense Emergency, NORAD region commanders notify FAA ARTC centers within their areas of responsibility of the alert and the extent of implementation of the plan. The ARTC centers, in turn, will disseminate the appropriate portions of the alert to civil and military air traffic control facilities under their jurisdiction.

Each civil and military ATC facility must maintain a current SCATANA action form for that facility and execute the instructions thereon at the direction of the ARTCC.

10781

Testing Procedures

To insure that SCATANA actions can be taken expeditiously, tests are conducted at frequent intervals. The tests are originated at the NORAD region level. All Federal facilities responsible for SCATANA actions must participate. The participation and reporting are prescribed on the SCATANA actions form for a particular facility. During such tests, all actions are simulated.

Senior AC's must be familiar with SCATANA and the facility's SCATANA action form to provide for expeditious action and handling of an alert or tests. An internal procedure for dissemination of an alert or test is necessary to insure that those concerned or affected at a facility receive notification and accomplish the required action in minimum times.

SAFETY

Safety is definitely one of the most important areas of responsibility with which supervisors must concern themselves. Recognizing the potentially hazardous conditions associated with electrical and electronic equipment, knowing how to prevent such conditions or what to do if confronted with them, and imparting this awareness to personnel for whom responsible, are major responsibilities of all senior AC's.

The safety program may necessarily be a general one; i.e., it must extend to every facet of an operation and apply equally at all levels. Safety is everyone's responsibility. Unsafe conditions must be reported to appropriate authority, other personnel must be warned when endangered, any injury or evidence of impaired health must be reported, and in the event of an emergency or some hazardous condition, reasonable caution must be exercised appropriate to the situation.

One approach to the safety program may be to insure that personnel are aware of the hazards that exist and the precautions that must be taken or observed. For example: indoctrinate them that a 60-hertz alternating current passed through a man's body from hand to hand or from hand to foot, with gradually increasing current, causes a perceptible shock at one milliampere, voluntary control of muscles becomes impossible at 10 milliamperes, and one second or more at 100 milliamperes or over generally proves fatal. The following precautions should be observed:

1. Lock and tag switches open before anyone works on a circuit.
2. Never bridge a fuse.
3. Consider all circuits alive until proven otherwise.
4. When someone is working on high-voltage equipment, make sure that another person is present that is capable of rendering assistance or first aid in an emergency.
5. Do not energeize equipment if there is evidence of water leakage.
6. Make certain that all ground connections to electrical equipment are inspected and cleaned periodically and that they are not painted or greased.
7. If use of CO_2 is necessary to extinguish an electrical fire, consider the danger of suffocation from prolonged exposure in confined spaces.
8. Rope off and place danger signs in hazardous areas.

Indoctrinate personnel that electromagnetic radiation, depending upon the intensity, can produce harmful biological effects in humans, cause spark ignition of volatile combusibles, or actuate electroexplosive devices contained in aircraft ordnance systems. The following precautions should be observed:

1. Minimize the hazard by increasing the distance between the energy source and the item to be protected or by reducing the power output of the radiation at its source.
2. Park aircraft employing high-power radar so that the beam is directed away from working areas, fueling operations, and ordnance loading.
3. Post warning signs at the limits of hazardous areas subject to entry by personnel.

Indoctrinate personnel that all solvents will dissolve the natural skin oils and may cause skin irritation or burns and they are toxic causing an inhalation hazard to exist. The following precautions should be observed:

1. Avoid prolonged or frequently repeated contact with skin.
2. Wear rubber gloves when using solvents.
3. Work in a well-ventilated area or wear a protective mask.

Indoctrinate personnel that carbon monoxide, a normal byproduct of all combustion engines, is a colorless, odorless, and tasteless gas which is extremely hazardous. When inhaled by an individual, it inactivates and absorbs the blood hemoglobin, which in a very short time causes unconsciousness and possibly

10782
18101

death. Never allow anyone to work on or around a combustion type engine such as power units of emergency generator systems without adequate ventilation.

The safety program may not lend itself to any well-defined system which should be followed and practiced in all situations but it must be brought to everyone's attention frequently as a reminder. Any infraction of accepted safe procedure should be corrected and dealt with accordingly.

LETTERS OF AGREEMENT

Letters of Agreement, after appropriate approval, are official documents describing specific procedures and jurisdiction concerning air traffic mutually agreed upon between ATC facilities. Requirements for issuing Letters of Agreement are varied and in general include the following:

1. Supplement established operational or procedural instructions.
2. Define interfacility coordination requirements concerning control of air traffic.
3. Establish or standardize operating methods.
4. Describe special operating conditions or specific air traffic control procedures.
5. Delegate areas of control jurisdiction and conditions of their use.
6. Describe procedures or minimums that differ from normal standard procedures to satisfy a requirement of a user activity.

DEVELOPMENT

A Letter of Agreement is a jointly executed agreement. However, through coordination of affected facilities, the responsibility for development and processing of such Letters is determined and assigned to a single facility. Letters of Agreement depicting naval operations are normally prepared by the affected naval facility. Although the responsibility is ultimately the commanding officer's, senior AC's are necessarily involved and frequently responsible for development of the original Letter for approval of higher authority.

When developing Letters of Agreement, the following guidelines should be followed:

1. Confine the material in each Letter to a single subject or purpose.
2. Describe the responsibilities and procedures applicable to each facility and organization involved.
3. Attach charts or other visual presentations, when appropriate, to depict the conditions of the agreement.
4. Delegate responsibility for control of IFR traffic by describing the area affected, defining the conditions of use of the area, specifying the details of the control procedures to be used and communications and coordination requirements.
5. Coordinate with other facilities and agencies as appropriate.

APPROVAL

After the necessary coordination with affected facilities and the basic Letter is mutually agreed upon locally, two copies of the proposed Letter are sent to the FAA regional office for review. This may not be required where local FAA officials possess authority to approve such documents. In any case, the local FAA officials will normally handle the proposed Letter as far as FAA review and approval are concerned.

After review and approval of the proposed Letter by the FAA, the responsible facility will prepare the Letter in final form including incorporations of instructions as a result of the FAA review. An effective date should be established allowing sufficient time after distribution for facilities and controllers affected to become familiar with the conditions of the agreement. Additionally, Letters of Agreement between naval facilities and the FAA must be approved by the Chief of Naval Operations before they are official.

CONTROLLER CERTIFICATION, RATING, AND PROFICIENCY

Commanding officers of Navy and Marine Corps shore activities operating ATC facilities must insure that only personnel who are certified in accordance with FAR 65 and qualified in accordance with OpNav 3721.1 (Series) and local facility directives are permitted to control air traffic. Additionally, air traffic controllers under training must be properly supervised by qualified controllers.

FAR 65 established the requirement of possession of basic FAA certification (Airman written examination report). Then, qualification by operating position is accomplished locally;

10783

and when an applicant has qualified for all operating positions at a particular control tower, he is issued a "facility rating."

Surveillance and precision radar controllers, in addition to the basic FAA certification, must be graduates of the GCA controller school and be qualified in accordance with local directives. Commanding officers must insure that an appropriate entry is made in an individual's service record when considered qualified to control aircraft under instrument conditions using surveillance or precision radar.

A facility's training program must necessarily be a continuous operation for the various levels of certification and ratings required. Keeping the number of qualified controllers at the required level is a never-ending problem considering the Navy's duty assignment rotation system. Senior AC's may be directly responsible for the training program itself, and in every case will have definite responsibilities within the various phases of training.

The officers and enlisted crews of the ATC facilities should train at the activity as a team and as such are considered watch standers.

Training of controllers in positions other than those at which they are qualified should be conducted in VFR conditions. Nonqualified controllers in training must be under the direct supervision of a qualified controller when actually engaged in the control of aircraft.

Cross training in as many operating positions as possible is desirable for ATC personnel to provide the flexibility of rotating controllers throughout the air traffic control division.

Information required to qualify controllers at each operating position must be included in local ATC facility operating instructions, except when such information is readily available in other publications. All information required to train and qualify controllers must be kept current and readily available.

Officer and enlisted radar operators must develop and maintain proficiency by controlling at least 5 approaches per week. Where the amount of air traffic limits proficiency, those controllers qualified to control IFR traffic may concurrently count those trainee controlled approaches they actively monitor.

EXAMINERS

CTO examiners are designated by the FAA in sufficient numbers and locations to meet the certification and rating requirements. All FAA tower chiefs, the FAA chief controllers at jointly operated Navy/FAA facilities, and FAA air traffic representatives at military approach control facilities are designated as examiners. The examiners are authorized to conduct the written and practical examinations prescribed by FAR 65.

Where FAA examiners are not sufficient or available to satisfy the needs of a military facility's certification and rating needs, military examiners may be appointed as required and requested by the military agency. This initial request is made to CNO (OP-534) for validation of the requirements. For other than the initial request, a commanding officer may communicate directly with the FAA Regional Office to obtain a Letter of Designation for an individual which signifies the designation of a military examiner by the FAA. CNO (OP-534) must be informed in the latter case. Personnel recommended as military examiners must meet the eligibility qualifications listed in Handbook 7220.6 (Series) for examiners.

MONITORING CONTROLLER PROCEDURE

The FAA has been authorized and requested to report results of in-flight monitoring of air traffic control procedures employed by Navy/Marine Corps air traffic facility personnel. In reporting the results and making recommendations concerning the procedures checked, the FAA personnel communicate directly with the facility commanding officer or his authorized representative. The report is made by completion of an FAA form entitled ATS Facility Monitor Report. If conditions allow, the FAA personnel may discuss the check informally with the facility personnel.

Senior AC's supervisory positions should insure that the FAA flight monitor personnel and/or the reports are appropriately received and that the recommendations or comments are taken in the constructive manner in which offered. The discrepancies noted should be reviewed and corrected as feasible. A careful analysis of any derogatory comments should be made and consideration given to

10784

recommendations. The supervisor can make good use of the recorder tape in a review of this type and preferably in company with the controllers affected. The proper attitude toward and the use of these reports will assist supervisors in maintaining a high degree of professionalism among controllers.

FAA AIR TRAFFIC REPRESENTATIVES

At certain locations where approach control authority has been delegated to the military, an FAA representative may be assigned on a resident basis. The Navy considers such liaison representation with the FAA important to maintain an efficient and effective operation of Navy approach control service. The responsibilities and authority of such representatives include the following:

1. Conduct continuous inspections to insure that the equipment performance and assigned personnel meet acceptable standards.
2. Suspend approach control authority in the interest of safety considering sufficient numbers and proper certification of facility personnel and operation in accordance with jointly agreed upon control procedure.
3. Recommend changes to improve the scope of service provided, personnel training and certification, and development and utilization of improved procedures for increased efficiency.

Deficiencies or discrepancies noted by such representatives are normally brought to the attention of the ATC facility officer for correction, except that when the time element involved would jeopardize the safety of flight, on-the-spot action may be taken prior to the normal notification procedure.

NAVY APPROACH CONTROL FACILITIES

The Federal Aviation Administration (FAA) has statutory authority and the responsibility for the provision of air traffic control service to promote the safe, orderly, and expeditious flow of air traffic within designated controlled airspace. Accordingly, the authority for the conduct of approach control service rests with the FAA. However, by mutual agreement between the FAA and the cognizant military service, approach control authority may be delegated to the commanding officer of a military aviation activity. This authority is for the primary purpose of providing approach control service for military installations, but may include civil airports located within the designated controlled airspace. When so delegated, approach control authority may be exercised through a tower, mobile or fixed ASR/PAR facility, Radar Air Traffic Control facility, or a combination thereof, utilizing the standardized procedures prescribed by FAA Terminal Air Traffic Control Handbook 7110.8 (Series). Military air traffic control personnel conducting approach control operations must be qualified and certificated in accordance with the FAA Certification and Rating Handbook 7220.6.

In the interest of economy, the FAA has been invited to utilize naval radar air traffic control facilities to provide approach control service for certain terminal areas encompassing naval aviation shore activities. When the FAA chooses to exercise this option, such facility is designated a joint USN/FAA facility and approach/departure control is conducted therefrom for all airports within the designated controlled airspace. General guidance regarding the administration and operation of joint USN/FAA facilities is contained in applicable provisions of OpNav Inst. 3722.7 (Series).

FACILITIES FLIGHT CHECK

Safety of flight and effective control of aircraft movements necessitate that the components of air navigation systems be accurate, adequate, and reliable, Various types of navaids are in use, each serving a special purpose in the system of air navigation. Experience has shown that electronic navaids do not always provide accurate information even though ground monitoring equipment indicates normal operation. A physical check of navaids must be conducted to determine the degree of accuracy to insure continued reliable operation.

The FAA, having statutory responsibility for the operations and maintenance of the common system of air navigation and traffic control within controlled airspace, conducts the flight checks of navaids based on jointly agreed standard flight inspection procedures. These procedures are contained in the U.S. Standard Flight Inspection Manual.

3350 10785

AUTHORITY AND RESPONSIBILITY OF FLIGHT INSPECTORS

Standard flight inspection procedures require specially equipped aircraft and specially qualified aircrews. Because of the influence and importance of a flight inspector's position, only the highest caliber personnel are assigned this duty.

The authority and responsibilities of a flight inspector include the following:

1. Schedule and conduct flight inspections of navaids and ground communications equipment in accordance with established procedure.
2. Determine the adequacy of the facility to fulfill its required function.
3. Certify the operational status of facilities based on the results of a flight inspection.
4. Coordinate with maintenance personnel in the correction of malfunctions noted.
5. Report the results of the flight inspection to the appropriate authority.
6. Analyze and evaluate the overall performance of all services provided for use in air navigation by a facility.
7. Determine minimum reception altitudes of navaids and communication equipment.
8. Conduct initial and periodic flight inspection of reporting points.

TYPES AND PRIORITY OF FLIGHT INSPECTIONS

Official flight inspections are of five basic types as follows:

1. Site evaluation. To determine the suitability of a proposed site for a permanent installation.
2. Commissioning. A comprehensive flight inspection to determine that the facility will support its operational requirements.
3. Periodic. A regularly scheduled flight inspection to determine that the facility will still meet the standards for a commissioned facility.
4. Special. A flight inspection required by special circumstances to determine facility performance or characteristics.
5. Surveillance. An unscheduled flight inspection of commissioned aids to determine that performance continues to meet applicable standards.

Priorities of flight inspections are assigned to provide for an order of accomplishment when such inspections are required for more than one purpose at the same time. Generally speaking, all Special flight inspections are first priority; all Site and Commissioning inspections are second priority; and Periodic and those Special inspections for the purpose of adjusting a navaid that is already within acceptable tolerance are third priority.

FREQUENCY OF RECURRING FLIGHT INSPECTIONS

A schedule of periodic flight inspections is contained in the Flight Inspections Manual specifying the minimum number of inspections required annually and the number of days between inspections. This schedule is the minimum requirement. In some cases it may be necessary to conduct inspections more frequently to assure satisfactory performance.

Generally, the requirements for periodic flight inspections of each individual navaid are satisfied by complete inspection of that aid. However, some navaids such as TACAN and DF lend themselves to a partial inspection on a progressive basis. In this manner, requirements for checking all the required items are satisfied within the specified number of days between inspections.

GENERAL FLIGHT INSPECTION PROCEDURE

Except for periodic flight inspections, the usual procedure to initiate a flight inspection is by a request from appropriate authority. A request for a flight inspection should not be initiated unless all ground equipment is in place, properly adjusted and calibrated, and operating normally. Upon receipt of a request for a flight inspection, authority within the flight inspection organization will notify the facility of the ETA of the flight inspection aircraft. No request or advance notice of arrival is required for a periodic or special flight inspection, but it is often desirable to permit ground personnel to schedule their activities to allow participation in the inspection.

power and range resolution necessary for this type of altitude determination.

ECM Deception

The pulse compression radar depends on the phase and frequency characteristic of the transmitted pulse to determine whether or not to accept a returned signal. If the phase and frequency do not match the transmitted pulse, compression will not take place and the signal will not pass through the receiver.

Signal-to-Noise Ratio

Due to the response of the matched filter to the definite phase and frequency characteristic of the transmitted signal, and the attenuation of other signals, the pulse actually applied to the receiver has a signal content much higher than its content of random noise. The signal-to-noise ratio of the system will be improved by a factor equal to the compression ratio over conventional radar.

Target Velocity

Target velocity can be rapidly determined by the use of a computer and sideband inversion. If a signal receives up Doppler, after sideband inversion the shift will appear as down Dopper. By shifting the local oscillator frequency above and below the returned echo on alternate pulses, the Doppler can be changed from up to down alternately with each transmitted pulse. This will produce a shift equal to twice the normal Doppler shift and will make it possible to determine target velocity in a time equal to two PRT. This principle could be easily incorporated. Sideband inversion is explained in detail later in this discussion.

PULSE EXPANSION

The pulse expansion operation will utilize a 0.1-μsec pulse and expand it to 1-μsec. Then stagger delay (frequency) the 1-μsec pulses to form a 10-μsec chain of pulses for transmission. The overall operation is to generate a 0.1-μsec pulse and, after expansion, transmit a 10-μsec pulse.

Spectrum Generation

RF energy is generated by a Coherent Master Oscillator (COMO) which is gated with a square wave of the desired time duration. For discussion purposes we will use a COMO with a center frequency of 100 mc which is gated for 0.1-μsec at a PRF of 300 cps. When this pulse is produced, it contains not only the basic frequency, but also many other frequencies within a spectrum as illustrated in figure 15-15. While the difference between each frequency is determined by the PRF, the pulse width determines the bandwidth and therefore the number of frequencies within the spectrum is controlled by both PRF and pulse width.

In figure 15-15 the frequency which has the largest amplitude is the resonant frequency of the signal source by means of which this spectrum was created. Numerous other frequencies result on either side of f_o. Those above f_o will be f_o plus one PRF, f_o plus 2 PRF's etc. At this rate, numerous different frequencies are present, each 300 cps apart, and each smaller in amplitude as these frequencies approach the upper bandwidth limit.

Those below f_o will be f_o minus one PRF, f_o minus 2 PRF's, etc. At this rate numerous different frequencies would be present, each one lower in frequency by 300 cps, and each one lower in amplitude as the lower bandwidth limit is approached.

Since the COMO is gated for 0.1-μsec of time, the COMO will generate a spectrum with a bandwidth of 20 megacycles. Bandwidth is determined by dividing the pulse width into 2. NOTE: In order to receive and to reproduce satisfactorily rectangular pulses equal in amplitude to the noise voltage, the receiver bandwidth in cycles per second should be approximately 2, divided by the pulse width in seconds. Therefore, a 0.1-μsec pulse width will generate a 20 megacycle spectrum bandwidth. Because each different frequency between the bandwidth is 300 cps apart, over a

Figure 15-15. —COMO output

1076

In preparation for the flight inspection, a thorough understanding between ground personnel and the flight inspection team is essential for a successful inspection. In the interest of making an efficient flight inspection, certain preparations are required of ground personnel so as to insure adequate communications, provide for availability of maintenance personnel, insure that controller personnel are briefed on the altitudes and areas to be flown when in congested areas, etc.

Normally, the flight inspection is technically an operation between the inspection team and maintenance personnel concerning the error of the equipment, etc. However, controller personnel are utilized by the inspection team concerning air traffic control during the in-flight inspection; and although the controllers are not evaluted, apparent controller deviations will be noted during inspections of the entire facility.

Where dual equipment is provided, both sets of equipment must meet the same tolerances. On some types of equipment, both sets must be thoroughly checked while for other types a spot check and comparison of operation are sufficient. Details for each type navaid are included in the Flight Inspection Manual section on that particular navaid. Additionally, standby power supplies will be checked on the commissioning inspection only unless there is suspected deterioration while the standby source of power is in use.

Upon completion of the flight inspection, the inspector will discuss the inspection with ground personnel, determine facility status, and prepare the appropriate reports. An informal discussion is usually best to acquaint ground personnel with problems encountered during the flight inspection. This is especially true in the case of DF and radar inspections where the human element is involved. Whenever possible, such discussions should be held directly with the personnel concerned.

The flight inspector will determine the facility status and insure the appropriate ground personnel are advised.

FACILITY STATUS CLASSIFICATION

The facility status classification indicates the general extent of usability as determined from each inspection. The flight inspector will assign one of the classifications as follows:

1. Unrestricted. The facility meets all tolerances and is fully usable within its service volume (specific limits of distances and altitudes).
2. Restricted. The facility meets established tolerances within its service volume except in specific areas which must be clearly defined in the various publications available to users.
3. Unusable. The facility is unsafe, unreliable, and unusable for air navigation.

FLIGHT INSPECTION PROCEDURES FOR CONTROLLERS

No specific tolerances are established for controllers during flight inspections; however, supervisors should insure that experienced controllers are available. Apparent participating controller deviations are normally brought to the supervisor's attention.

For flight inspections of DF aids, controllers must be able to direct the aircraft over the station, report station passage, and provide pertinent information relative to the DF service. The inspector determines whether or not the entire system is safe and reliable. If a DF approach has been established for emergency use, the controller must be able to direct the pilot into a position from which a safe landing can be made.

Controllers that participate in flight inspections of ASR and PAR equipment should be experienced personnel and familiar with the flight inspection objectives. They should participate in the initial meetings prior to the flight inspection where scope operation, target interpretation, and other techniques are mutually agreed upon. To determine the usability of the entire system, an evaluation of the controller performance, in addition to checks of the system accuracy, is necessary. It is difficult to determine the exact degree to which equipment or controllers contribute to overall performance. Any tendency of controllers to give erroneous advisories or instructions, or become confused during a simulated emergency, should be noted regardless of how well the equipment works. While it is not feasible to

evaluate each controller, several approaches should be made to obtain an overall viewpoint. Appropriate remarks regarding controller performance are entered on the flight inspection report.

FAA EQUIPMENT CERTIFICATION

A vast, complex system of air traffic control and navigational aid facilities enables large numbers of aircraft to move efficiently and safely within the National Airspace System. This includes FAA, military, and non-Federal facilities designated for use in the National Airspace System.

In addition to the flight inspection procedure discussed earlier, the FAA has established a ground inspection procedure for air traffic control and navigational aid facilities. The actual inspection is made by technical personnel in accordance with appropriate performance standards and tolerances which will assure continual accuracy and reliability of the system. The publication governing ground inspection is entitled U. S. Interagency Ground Inspection Manual, Air Traffic Control and Navigational Aid Facilities. It is promulgated within the Navy as OpNav Instruction 3721.18. The inspections and technical performance standards prescribed in this manual apply to all military ATC and navaid facilities DESIGNATED for use in the National Airspace System. The required ground inspections are a responsibility of the cognizant maintenance authority for the facility or facilities. Cognizant military authority forwards certification, based upon the maintenance authority's assurance of operation within the prescribed tolerances, to the appropriate FAA operational authority that the facility is functioning properly.

When it has been determined, either by flight check or by ground inspection, that a facility does not meet prescribed technical performance standards or tolerances, the cognizant maintenance technician must notify the air traffic control officer having operational jurisidiction over the facility and provide appropriate technical information on which to base a NOTAM. In addition to military NOTAM action the appropriate FAA authority must be notified and a civil NOTAM will be issued.

Notification of scheduled maintenance shutdowns of military facilities which have been certified for use in the National Airspace System must be submitted to the appropriate ARTCC for concurrence in sufficient time to allow for NOTAM issuance at least 5 hours prior to the shutdown.

AIRFIELD AVAILABILITY

The Navy's policy is that naval airfields must be available for the use of military aircraft to the maximum extent possible, and that the aircraft and crew must be supported to the fullest extent possible within the capabilities of the facility.

Transient military aircraft cannot be prohibited from landing at any naval airfield except when:

1. An emergency situation exists.
2. Construction hazards, etc., render the airfield useless.
3. CNO has authorized prohibition.
4. The airfield is in a caretaker or inactivated status.
5. Due to special operations or activites.

Any restrictions placed upon aircraft operations for safety reasons, such as inspections, public events, etc., must be limited to only that time period during which the hazard actually exists.

Commanding officers of stations located on airfields which are used jointly with civil or other military agencies can only impose restrictions which are applicable to naval facilities under their control.

In local areas containing several naval airfields, the duplication of facilites at each of the airfields to fully accommodate transient aircraft is not required if one of the fields can provide for the needs of transients. However, any restrictions imposed must be approved by CNO.

Commanding officers furnish OCEANO with pertinent information concerning the hazards, hours of operation, field condition, etc., for publication in the appropriate DOD FLIP.

Official business only indicates the field is closed to all transient military aircraft except those on official business at, or near, the airfield. Official business is further defined

10788

as the necessity for personnel aboard an aircraft to contact personnel, units, or organizations at, or near, the airfield most conveniently located for the service of and in the interest of the Government. This does not provide for use of the airfield by transient military aircraft for the purpose of obtaining clearance, services, or other items attendant to itinerant operations. Official business only restrictions do not apply in case of emergencies or for designation of the airfield as an IFR alternate. Permanent official business only restrictions must be approved by CNO.

Navy commanders cannot permanently restrict any military aircraft from landing at their airfields unless CNO has approved of the restriction. Emergency restrictions of a temporary nature (10 days or less) may be imposed by commanding officers without higher authorization when landing of aircraft at their airfields is considered unsafe.

10789

CHAPTER 4

TERMINAL INSTRUMENT PROCEDURES

To safely satisfy the instrument approach and departure requirements of the present air traffic volume and the ensuing increases, continuing emphasis is placed on establishment, review, and updating such procedures. The Terminal Instrument Procedures (TERP's) handbook, OpNav 3722.16 (Series), prescribes standardized methods to be used by all personnel charged with the responsibility for the preparation, approval, and promulgation of terminal instrument procedures. This handbook, however, is not a substitute for sound judgment and common sense, and does not relieve personnel so charged from exercising initiative or taking appropriate action in recognizing the capabilities and limitations of navaid equipment and aircraft performance as associated with terminal instrument procedures.

ESTABLISHING APPROACH PROCEDURES

The Navy establishes and approves terminal instrument procedures for airports under its jursidiction. Navy terminal instrument procedures are official procedures. The FAA should be notified when military procedures are canceled.

RESPONSIBILITY AND JURISDICTION

Commanding officers of Navy and Marine Corps shore installations supporting flight operations must establish terminal procedures that provide instrument approach capability for local and transient flight operations. The procedures must conform to the appropriate provisions of OpNav's 3722.16 (Series) and 3770.2 (Series). The Naval Oceanographic Office is designated as the review and approving authority for all Navy/Marine Corps terminal approach procedures. Where waivers are required, they will be referred to CNO by the Oceanographic Office for approval. All minimums established must be the lowest permissible consistent with mission accomplishment and flight safety.

COORDINATION WITH FAA

During the formulation of approach procedures, coordination must be effected with the ATC activities that provide the associated en route and approach control services. ATC concurrence in the optimum approaches available must be sought. In the event that the existing airspace structure in and around the terminal area is not suitable for optimum procedures, the appropriate Navy Regional Airspace Officer (NARASPO) or a Command Airspace Liaison Officer should be consulted for assistance. Planned cancellation of procedures must be coordinated with ATC activities concerned. When practicable, this coordination should be effected well in advance of the planned effective date of cancellation.

NUMBERING APPROACHES

Terminal instrument procedures should be numbered to be meaningful to the pilot, and to permit ready identification in air traffic control phraseology.

When the angle between the final approach course and the runway centerline meets the straight-in landing criteria, the approach should be numbered to identify the type of facility which provides final approach guidance and the runway with which the final approach course is alined. Examples: VOR RWY 15; TACAN RWY 21.

10780

When military operational requirements necessitate that more than one procedure be published to serve the same runway, using the same navaid, they should be numbered to indicate the difference. Examples: TACAN 1 RWY 18; TACAN 2 RWY 18.

Where the straight-in landing criteria are not met and the procedure is published with circling minimums only, it should be named to identify the type of facility which provides the final approach course guidance. The first procedure formulated for a type of facility should be given the suffix A, even though there may be no intention to formulate additional procedures. If addtional procedures are formulated, they should be lettered in sequence. Examples: VOR-A; VOR-B. A revised procedure should retain the original letter suffix.

AC.2

Figure 4-1.—Minimum safe altitudes.

PROCEDURE DESIGN

The minimum number of approach procedures should be established at a given facility consistent with the mission requirements.

Aircraft performance differences have a direct effect on the airspace and visibility needed to perform certain maneuvers, such as circle to land, turning missed approach, final alinement correction to land, and descent. To compensate for these differences, all aircraft are divided into five categories, designated category A through E, based on landing speed and weight characteristics. The approach category characteristics must be considered when determining turning radii, minimums, and obstruction clearance areas for circling and missed approaches. Military aircraft category data is published in FLIP Planning Section I. Each low altitude procedure should prescribe minimums for category A, B, C, and D aircraft. Each high altitude procedure should prescribe minimums for category C, D, and E aircraft.

A minimum safe altitude should be established for emergency use which provides 1,000 feet obstruction clearance in a sector of a circle with a 25-mile radius from the facility upon which the procedure is predicated. The sectors should not be less than 90 degrees, and the obstruction clearance should also apply to adjacent sectors and the periphery of the sector within 4 miles of the sector division lines. (See fig. 4-1.) Establishment of minimum safe altitudes is not mandatory in high altitude procedures. These criteria do not apply to radar procedures.

Emergency safe altitude is the lowest altitude for emergency use which provides 1,000 feet (2,000 feet over designated mountainous terrain) obstruction clearance within a 100-mile radius of the facility upon which the approach procedure is predicated. Emergency safe altitudes are established at the option of the approving authority and are the responsibility of OCEANO for naval procedures.

Terminal transition routings should begin at a navaid or fix by which the en route structure is defined and terminate at the initial approach fix of an approach procedure. Transition routings may be direct from the en route navaid or fix or via another navaid known as a "feeder" facility. Any navaid or fix, including en route structure facilities, used by ATC authorities in connection with the particular approach may be selected as a "feeder" facility. The navaids selected for transition routings must, whenever practicable, be within the frequency range of the instrument approach facilitiy; i.e., VORTAC

SE70110791

for TACAN procedures, etc. Coordination of these routings with the appropriate ARTCC must be effected. Changes to such routings that occur between the times the approach procedures are reviewed annually must be reported to NAVOCEANO for the necessary chart revisions.

An instrument approach procedure may have several separate segments; i.e., initial, intermediate, final, and missed approach segments. In addition, an area for circling the airport under visual conditions should be considered. The approach segments begin and end at designated fixes; however, under some circumstances, certain segments may begin at specified points where no fixes are available. The fixes are named to coincide with the associated segment. For example, the intermediate segment begins at the intermediate fix and ends at the final approach fix. (See fig. 4-2.) Only those segments which are required by local conditions need be included in a procedure. In constructing a procedure, the final approach course should be identified first because it is the least flexible and most critical of all the segments. When the final approach has been determined, the other segments should be blended with it to produce an orderly maneuvering pattern which is responsive to the local traffic flow.

Approach and missed approach procedures should be so designed as to avoid the necessity for navaid, SIF code, and frequency changes at altitudes below 2,500 above the ground. Where facilities have the required communications capability, procedures designed primarily for high performance single piloted aircraft, or aircraft without dual radio capability, should be designed to eliminate the need for frequency changes after commencing approach.

Initial Approach Segment

The instrument approach as such commences at the initial approach fix (IAF). In the initial approach the aircraft has departed the en route phase of flight and is maneuvering to enter an intermediate segment. It may not be necessary to designate an initial approach segment, depending upon local conditions, in which case the approach commences at the intermediate fix (IF). An initial approach may be made along an arc, radial, course, heading, radar vector, or a combination thereof. Procedure turns and high altitude teardrop penetrations are initial approach segments. Where holding is required, prior to entering the initial approach segment, the holding fix and the initial approach fix should coincide.

Intermediate Approach Segment

This is the segment which blends the initial approach segment into the final approach segment. It is the segment in which aircraft configuration, speed, and positioning adjustments are made for entry into the final approach segment. The intermediate segment begins at the IF or point, and ends at the final approach fix (FAF). This segment may be based on an arc, course, or radial.

Final Approach Segment

This is the segment in which alinement and descent for landing are accomplished. The final approach segment considered for obstruction clearance begins at the FAF or point and ends at the runway, airport, or missed approach point, whichever is encountered last. Final approach may be made to a runway for a straight-in landing, or to an airport for a circling approach.

NOTE: Refer to the applicable sections of the TERP's handbook for specific obstruction clearance areas, required obstruction clearance, final approach course alinement and other detailed procedure since it is not considered practical to include these items in this training manual.

Minimum Descent Altitude (MDA)

The MDA is the lowest altitude to which descent is authorized in procedures not using an electronic glide slope (nonprecision). Aircraft are not authorized to descend below the MDA until the runway environment is in sight, and the aircraft is in a position to descend for a normal landing. The MDA must be expressed in feet above MSL and is determined by adding the required obstruction clearance to the MSL height of the controlling obstruction in the final approach and circling approach areas.

The MDA for a straight-in landing approach must provide at least minimum obstruction clearance of obstructions in the final approach area and meet the requirements for the missed

10792

AC. 3

Figure 4-2. —Approach segments.

10793

approach transition. Additionally, the MDA for a circling approach must provide minimum obstruction clearance in the circling approach area.

Decision Height (DH)

The decision height applies only where an electronic glide slope provides the reference for descent, as in PAR. The DH is the height, specified in feet above MSL, above the highest runway elevation in the touchdown zone (first 3,000 feet of the runway beginning at the runway threshold) at which a missed approach should be initiated if visual reference has not been established. DH's must be established with respect to the appropriate obstruction clearance requirements.

Missed Approach Segment

A missed approach procedure should be established for each instrument approach procedure. The missed approach should be initiated at the decision height in precision approaches or at a specified missed approach point in nonprecision approaches. The missed approach procedure should be simple, specify an altitude, and whenever practicable, a clearance limit. The missed approach altitude specified in the procedure should be sufficient to permit holding or en route flight.

Whenever practicable, the missed approach course should be a continuation of the final approach course. Turns are permitted, but should be minimized in the interest of safety and simplicity. When a turn of no more than 15 degrees is made, the missed approach is considered straight.

The missed approach point specified in the procedure may be the point of intersection of an electronic glidepath with a decision height or MDA, a navigation facility, a fix, or a specified distance from the final approach fix. Specific criteria for the missed approach point (MAP) are contained in the appropriate sections of the TERP's handbook describing the various types of approaches. The missed approach obstruction clearance area is basically the same for all types of approaches except PAR which has a specific missed approach procedure to fit the situation.

PROCEDURE FLIGHT CHECK

Prior to submission for review and approval, each procedure should be flight checked by local aircraft for safety and operational suitability. When practicable, a separate check by an aircraft of each category for which minimums are included in the procedure should be accomplished.

RADAR PROCEDURE

Radar procedures are similar in design to other type procedures in that an initial, intermediate, final, and missed approach segment may be established. Course guidance in the initial and intermediate segments may be provided by radar or other navaid facilities. Where radar is the primary means of navigation, radar patterns and altitudes must be established, and altitudes must provide the required obstruction clearance for a specified distance either side of the designated pattern course. Where other navaids are used, the appropriate criteria for the particular navaid apply.

Vectoring altitudes may be established by dividing the area within operational radar coverage into sectors based primarily on existing obstructions. This establishes a minimum altitude within a particular sector for use when providing radar vectors.

Lost communications procedures must be established for radar approaches which include procedures for the pilot to follow in the event communications are lost with the radar facility. Where practicable, they should include a provision to execute a nonradar approach. If such a provision is not practicable, certain items essential for safe and orderly traffic management should be included such as the route to fly, clearance to a fix, altitude assignment, and the control facility to contact.

Unless otherwise indicated in the approach procedure, a single ceiling, visibility, and decision height approved for precision radar approaches will apply to all aircraft categories. Commanding officers, however, may specify PAR minimums by categories if required by application of TERP's criteria. In such instances a ceiling, visibility, and decision height for each aircraft category must be established.

10794

As a matter of policy, PAR minimums of ceiling 100 feet and visibility 1/4 mile may only be established when the runway concerned is configured with high intensity runway lighting and an approach lighting system. Touchdown zone and centerline lighting are desirable, but not mandatory for the 100 and 1/4 minimums.

Circling minimums should be included in ASR procedures in addition to the straight-in landing minimums unless a straight-in landing ASR approach is available for each runway usable for IFR approaches, and provided that definite restrictions do not preclude circling approaches. Examples of such restrictions are limited radar coverage and nonavailability of certain runways during IFR weather conditions. When circling ASR minimums are not to be authorized—the submitted procedure should be so annotated.

APPROACH MINIMUMS

As previously stated, established minimums should be the lowest permissible consistent with mission accomplishment and flight safety, with the determining factors being the required obstruction clearance in the final approach segment and possibly the missed approach segment. In general, the straight-in minimums will seldom vary by aircraft category. The primary differences will occur for circling minimums, because the size of the area to be considered for obstruction clearance varies by aircraft category. This may require consideration of different obstructions for different category aircraft.

Additional restrictions are possible by application of the tables of standard minimums contained in the TERP's handbook. These tables specify the lowest minimums which may be prescribed for each type approach approved. Consideration is given for the various lighting configurations in the standard straight-in minimums table. In addition to the MDA for nonprecision approaches and the DH for precision approaches, a ceiling value must be established for military procedures which, when added to the airport elevation or the touchdown zone elevation, will result in an altitude above MSL that is equal to or greater than the MDA or DH. When determining the ceiling value, consideration must also be given to reportable ceiling values observed by weather service personnel. If a resultant DH is 275 feet above the surface, the ceiling value would necessarily be 300 feet, since ceilings are reported in 100-foot increments through 5,000 feet.

Visibility Minimums

Several factors must necessarily be considered when determining visibility minimums, as follows:

1. The distance necessary for the pilot to see the airport or runway and safely descend from the MDA or DH and accomplish a landing.
2. The distance from the final approach fix to runway threshold.
3. The runway centerline and final approach course alinement, etc.

No single factor can determine the required visibility, and the various factors will vary with the different types of approaches and local conditions. The TERP's handbook contains tables of minimum visibilities which must be applied in addition to consideration of requirements of the individual approaches.

Runway visual range (RVR) minimums may be authorized for other than circling approaches at locations where an approved RVR installation is available.

Approved Lighting Systems

At installations where lighting systems are identifiable with standard lighting systems contained in the TERP's handbook, the visibility reduction afforded by such aids may be applied. For each procedure containing straight-in minimums to a specified runway, an indication should be made as to whether or not credit for lighting has been applied or is desired. Because of the variations in lighting systems installed at naval facilities, the Oceanographic Office, as the reviewing authority in coordination with NavAirSysCom, will ascertain whether or not the lighting installed qualifies for the reduced visibility credit. Application of lighting credit to reduce visibility minimums is not required.

10795

Figure 4-3.—Plan diagram of a PAR approach.

20-megacycle bandwidth, there are 66,666 different frequencies contained in this frequency spectrum.

Matched Filters

For this discussion our matched filter will consist of 10 channels. Each channel will have one or more amplifier (one of which must be tuned) and a delay line as shown in figure 15-16. Each channel has individual gain and frequency controls with a bandwidth of 1 mc. The amplifiers are tuned to successive frequencies 1 mc apart so that their response curves overlap at their half power points as shown in figure 15-17. The entire filter band pass will be 10 mc from the center of the above described spectrum. The filter will now respond to 33,333 different frequencies with each channel responding to 3,333 different frequencies. The 10 sections with their respective delay lines are connected with parallel inputs and all outputs connected to a summing amplifier to produce a single output.

The entire frequency spectrum bandwidth (20 mc) is applied to the input of each of the 10 channels through the delay line (all except channel 1 which has no delay line).

Each of the 10 channels is tuned so as to cover only a small part of the total frequency spectrum. Since there are only 10 channels, each with a bandwidth of 1 megacycle, only one-half of the overall spectrum is covered. Therefore, one-half of the spectrum is not passed through the matched filter because it is not within the half power points of any of the 10 channels.

This is necessary because the amplitude of the different frequencies is too great between the maximum and minimum. If the frequencies outside of the channel spectrum half power points are rejected, the amplitude difference between f_0 and f_1 or f_2 is now only 3 db. This allows the gain of the channel to be within practical limits.

As was previously determined, the numerous different frequencies within the entire spectrum bandwidth were separated from each other by

Figure 15-16. —Matched filter assembly block diagram.

1077

officers must periodically review terminal approach procedures at their facility and submit an annual report designated OpNav Report 3722-1. This report is scheduled in various months, depending on the geographical location of the facility. To determine when the report for your particular facility is required, refer to OpNav 3770.2 (Series). This report is confirmation that currently approved terminal approach procedures are operationally suitable and necessary, and that they conform to the provisions of the TERP's handbook and OpNav 3770.2 (Series). The report is accomplished by completion of an OpNav Form 3722/1 for high and low altitude ADF, VOR, or TACAN approaches and an OpNav Form 3722/2 for PAR and ASR approaches. Requirements for new or revised approach procedures that occur between annual facility reporting dates are handled in this same manner with the exception of the scheduled reporting dates. Senior AC's in the ATC division may be required to initiate this report by physically preparing the appropriate form(s) and insuring compliance with appropriate instructions for the commanding officer's review and approval.

Plan and profile obstruction diagrams of appropriate runway approach areas as depicted in Planning Standards (NavAir 00-100-505) must be forwarded with requests for approval of PAR procedures, unless a current diagram is on file at the Oceanographic Office. In addition, a diagram or chart showing the location and elevation of terrain and manmade obstructions within the prescribed obstruction clearance areas for each nonprecision and ASR approach, specifying the appropriate circling approach areas, must be included.

Figure 4-3 is an example of an enlarged, simplified plan diagram for a PAR approach to a particular facility. Figure 4-4 is a profile diagram of the same approach as shown in figure 4-3. In this particular case, controlling obstructions and other governing factors allow the transition directly from pattern altitude (initial approach) to final approach. Therefore, no intermediate approach is included. The profile shows obstructions and terrain considered and the PAR final approach surface slope ratio which will vary with the glide slope angle. In this case the glide slope angle is 3 degrees which requires a 34:1 ratio for the first 10,000 feet and a 29 1/2:1 ratio for the remaining final approach surface slope. No obstructions may penetrate this final approach surface slope to allow use of

AC.5

Figure 4-6.—Profile diagram of a TACAN approach.

this glide slope. Also shown is the missed approach obstruction clearance area and a 40:1 slope ratio of this area on the profile to show that no obstructions penetrate the missed approach surface slope and that the procedure is safe.

All the area sizes, slope ratios, and other technical information necessary to construct this diagram are contained in the TERP's handbook. Much of the information necessary to complete an OpNav Form 3722/2 can be taken from a diagram of this type.

Figure 4-5 is an example of a plan diagram for a low altitude TACAN approach. Although the profile is not required for a nonprecision approach, it may be considered helpful in determining obstruction clearance requirements, MDA's, missed approach points, etc. Figure 4-6 is an example of a profile diagram of the same approach as shown in figure 4-5. Again the specifications for constructing the diagram are contained in the appropriate section of the TERP's handbook.

Figure 4-7 is an example of a completed OpNav Form 3722/1 for the approach diagramed in figures 4-5 and 4-6. Keep in mind that when determining the minimums the appropriate table of standard minimums in the TERP's handbook must be considered in addition to required obstruction clearance.

PUBLICATION OF APPROACH PROCEDURES

To satisfy the primary requirement of having a current procedure in graphic form in the possession of the pilot and controller at the time of implementation, procedures should be submitted as far in advance of the implementation date is possible. They should normally be submitted no less than 60 days prior to the desired effective date to allow sufficient time for review and approval and for chart publication and distribution. The effective date will be assigned by the Oceanographic Office and will be calculated to coincide with the publication date of the charted procedure.

In order to provide sufficient time to effect removal of an approach procedure from the FLIP system, commanding officers should notify the NAVOCEANO approximately 30 days in advance of the effective date of the cancellation. Advance coordination of cancellations should be effected with the appropriate ARTCC authorities. The cancellation should be promulgated by NOTAM procedures when the next scheduled Terminal

COMMON CIVIL/MILITARY FORMAT

The TERP's handbook contains the approved criteria for formulating both civil and military instrument procedures requiring a format which includes ample information to satisfy the needs of both agencies.

The standard format normally provides landing minimums for approach categories A through D on low altitude (AL) approach charts, and C through E on high altitude (JAL) approach charts. Any category may be included on either chart when an operational advantage can be achieved. Only those categories of aircraft authorized to use a given procedure will be listed on the approach chart. The term not authorized (NA) is used when a particular category of aircraft is not authorized to use a specific approach. Figure 4-8 is an example of the landing minimum format portion of a low altitude approach chart.

The following is an explanation of terms not considered self-explanatory in figure 4-8:

1. DH (decision height) applies to precision approaches. The DH is the height MSL above the highest runway elevation in the touchdown zone at which a missed approach must be initiated if the required visual reference has not been established.

2. MDA (minimum descent altitude) applies to nonprecision approaches. The MDA is the lowest MSL altitude to which descent is authorized in procedures not using a glide slope until the runway environment is sighted.

3. HAA (height above airport) is for civil use and indicates the height of the MDA above the published airport elevation.

4. HAT (height above touchdown is for civil use and indicates the height of the DH above the highest runway elevation in the touchdown zone.

5. CEILINGS are values shown in parentheses for military use, and represent the lowest ceiling authorized for an approach. A ceiling is expressed in feet above the published airport elevation and is at or above the MDA or DH.

6. VISIBILITY values are expressed as runway visual range (RVR) shown in hundreds of

AC.7

Figure 4-8.—Low altitude landing minimum format.

feet, (24 equals 2,400 feet) runway visibility (RV), or prevailing visibility (PV), which are both shown in miles and fractions thereof.

Radar Minimums

Radar minimums are presently published in the FLIP IFR supplement in the aerodrome/facility directory section for the airport concerned. The information provided is basically the same as that provided on approach charts.

STANDARD INSTRUMENT DEPARTURES

A Standard Instrument Departure (SID) is an approved procedure that prescribes a route of flight with instructions for safely departing a runway and climbing to the en route structure. SID's are descriptions of air traffic control clearances. Their purpose is to increase the safety and efficiency of terminal flight operations by presenting departure clearances to pilots in graphic and textual form. Their proper use reduces pilot and controller workload and minimizes the probability of misunderstanding clearances. Additionally, the number and length of radio transmissions required for issuance of departure clearances are reduced.

POLICY FOR ESTABLISHMENT

Commanding officers of Navy/Marine Corps facilities are responsible for determining the

10801

152

need for SID procedures at their respective activities. Consideration will be given to transient as well as local types of operations when determining the need and in formulating SID's. The optimum SID provides for a direct climb on course from an airport to join an airway or route at a fix or facility. Extensive routing and/or maneuvering in the terminal area prior to proceeding on course should be avoided to the extent practicable when developing SID's.

Radar departures are considered to be a separate air traffic service and should not be included in SID's. However, this is not intended to preclude a route within a SID based on radar vectors in lieu of a route based on a navaid, or radar monitoring of a SID provided that vectoring aircraft off the prescribed SID routing is not undertaken as a monitoring function.

Senior AC's occupying the position in the chain of command which performs the physical function of air traffic control may be in the most ideal position to recognize the need for establishing, revising, or canceling SID procedures at their facility. Where the need is recognized, they should initiate action at the division level by presenting all the applicable facts and figures which would sustain the proposed procedure or action and the advantages possible.

Commanding officers of Navy/Marine Corps aviation shore facilities located within the contiguous U.S., Alaska, and Hawaii should request the appropriate FAA regional Air Traffic Division to assist in the development and/or revision of SID's for their activity. During the development or revision, coordination with local ATC authority and nearby civil or military airports must be effected. In obtaining desired routings, airspace limitations may create local coordination problems. In such instances, the appropriate NARASPO should be contacted for assistance.

At facilities where the FAA does not provide air traffic service, such as overseas, SID's may be established or revised as prescribed for CONUS except that FAA functions are not applicable. Commanding officers are responsible for formulation of SID's in coordination with the local ATC authorities of the host government.

After coordination of new or revised SID's has been completed, they should be forwarded to NAVOCEANO for review in conformance with OpNav 3770.2 (Series), and for approval, publication, and distribution in required quantities. A sketch of the SID should be submitted together with necessary textual information, delineating the appropriate ATC clearance to be charted. The sketch should depict actual flight paths from runway(s) to the start of the en route description to permit climb gradient computation.

Charting is accomplished in accordance with the appropriate SID chart specifications. Chart quantities desired for station usage should be made known to NAVOCEANO. Printing quantity requests should be based on an estimated 6 months' requirement. When existing stocks of SID charts are reduced to a point where reordering is indicated, the request for additional SID charts should be forwarded directly to NAVOCEANO since SID charts are not stocked in the distribution system.

SID's should be designated as either high altitude or low altitude, according to the route structure in which the SID is intended to terminate. If high and low altitude SID's are identical, they may be combined to be designated as high/low altitude SID's. The appropriate designation—high, low, or high/low—should be indicated on each SID pamphlet.

During local coordination, a mutually agreeable effective date for new or revised SID's should be decided upon. This date normally should be a minimum of 45 days after date of submission to NAVOCFANO to allow for review, approval, publication, and distribution.

DEVELOPMENT PROCEDURE

SID's may be implemented at any airport where terrain or other obstructions require specific departure restrictions. In addition, SID's may be established at any airport where they would be advantageous to air traffic control or pilots. The number of SID's implemented at a given facility should be kept to a minimum consistent with operational needs and the departure routes most frequently used.

When developing SID's, the following guidelines should be considered:

1. SID's may commence at the end of a runway, or basic departure routing procedures

for each particular runway may be included as part of a basic SID.

2. Radar vectors may be included in lieu of a route based on a navaid.

3. Routing should be the most direct and simplest possible.

4. The number of navaids used should be the minimum number possible.

5. Crossing altitudes/FL's should be kept to a minimum, based on radials of the same navaid, and may or may not be specified altitudes/FL's. If crossing altitudes/FL's are specified, they should be developed with consideration of the capabilities of the lowest performing type aircraft that would use the SID.

6. Noise abatement requirements should be considered.

7. SID's should terminate at an airway, radial, route, or fix.

8. SID's may have more than one transition from a common point.

9. More than one SID may have the same identical transition.

10. The description of the SID and transition, if appropriate, on the SID chart should be worded so that it can be easily understood.

The obstruction clearance criteria for SID's are contained in TERP's.

Minimum rate of climb information must be provided on published SID's which require a rate of climb greater than 150 feet per mile to obtain the required obstruction clearance. A rate of climb in excess of 300 feet per mile is not authorized.

Hazards, such as towers, buildings, terrain elevation, etc., which create a hazard to safety of flight in the event the departure procedure were not executed precisely, must be shown on the SID chart in their exact location to present a true relationship.

Naming and Numbering SID's

The designated name of a SID should correspond to a geographical location or a navaid along the SID route. The original SID should be assigned a name and the number 1; for example, Dutch 1 Departure. Old numbers should not be reused. The same or a similar name should not be assigned to different SID's within the same geographical location. When revisions or changes are made to the original SID, regardless of the degree of change, the SID should be renumbered.

Revisions or changes refer to items in the ATC clearance such as courses, altitudes, fixes, navaids, etc. Not included would be radiofrequency changes or chart detail other than the ATC clearance, or items involving flight safety such as climb gradients, etc.

If a SID is developed for specific types of aircraft, the adjective phrase to indicate this may be printed on the chart, such as Jet. If the SID is applicable to all types of aircraft, no specific description is necessary. The name of a transition should correspond to a navaid or a geographical location along the route to be flown. Cancellation of a transition route should not require a renumbering of the basic SID.

OPNAV REPORT 3722-2

An annual review of SID's to determine their consistency with operational needs and any revisions, additions, or deletions required must be made by commanding officers of Navy and Marine Corps facilities, and the result of this review is submitted to the Naval Oceanographic Office.

The annual reporting date for individual facilities is determined by the geographical location of the facility. To determine when the report for your facility is required, refer to the schedule contained in OpNav 3770.2 (Series). This report is designated OpNav Report 3722-2.

HOLDING PATTERN CRITERIA

The criteria for holding pattern airspace are contained in FAA Handbook 7130.3 and provide for separation of aircraft. However, when determining minimum holding attitudes based on required obstruction clearance, this same airspace area, with slight modification, is used.

APPLICATION TO THE ATC SYSTEM

Sufficient holding airspace areas should be planned and established to meet IFR traffic

0080110803

requirements within a facility's area of jurisdiction. Holding airspace area dimensions were developed to permit the following: Use of all types of en route navaids, reduction of holding airspace when optimum direction of entry is made, compatibility between patterns flown by reference to time and those flown by reference to DME, and selection/application of tailor-made airspace by furnishing several pattern sizes.

Holding pattern airspace areas should be pictorially displayed including captions to explain their use. Displays should be near appropriate controller positions and should be so constructed as to facilitate the maximum possible amount of traffic situations to preclude the requirements for controllers to determine holding airspace on the spot.

Good facility planning minimizes the need for unplanned holding at the control position. Unusual circumstances may require occasional unplanned holding; therefore, each control position should be analyzed according to altitude controlled and holding speeds normally encountered. When an analysis has been made, appropriate template sizes can be selected and captioned.

HOLDING PATTERN COMPONENTS

Efficient and economical use of airspace required standardization of aircraft holding procedures. All the variable factors such as navaid systems error, wind, aircraft speed, etc., which affect aircraft during holding maneuvers, were considered and incorporated into the holding pattern airspace criteria. Procedures were developed to accommodate the performance capabilities of pertinent civil and military aircraft.

The following basic components were developed as standard for the purpose of determining holding pattern airspace:

1. Outbound leg. The length of the outbound leg is based on time or distance. Standard time values are 1 minute for altitudes from minimum holding through 14,000 and 1 1/2 minutes above 14,000. Distance value of an outbound leg is not standard but must be established at a distance appropriate to the holding situation and in conformance with the tables for determining the DME leg lengths of holding patterns in Handbook 7130.3.

2. Maximum holding airspeed. Basic speed groups with compatible holding maneuvers were adopted. Aircraft are provided protected airspace based on the maximum holding airspeed. (See table 4-1.)

3. Angle of bank. Pilot procedure for entry and holding pattern turns is based on the result of pilot actions to establish and maintain a 30-degree angle of bank. To compensate for varying pilot technique, instrument precession, etc., the initial criteria used in determining the holding pattern area was 25 degrees angle of bank.

AIRSPACE DETERMINATION

The actual determination of airspace to be considered has been made relatively easy by establishment of a system of templates which allows selection of an appropriate template based on a aircraft's holding speed and altitude and the holding fix distance from the primary navaids. These templates are numbered 1 through 31, and each one is related to one or more even numbered altitudes/FL's. The templates were developed at a scale of 1: 500,000 which is the same as the Sectional Chart scale for easy application. A partial listing of speed group, fix distance, altitude/FL, and template number relationships is shown in table 4-2. Holding levels through 50,000 are provided at even 2,000-foot intervals. Holding at odd levels above 2,000 is based on the next higher even altitude/FL pattern.

DME APPLICATION

When establishing a DME holding, fix, the difference between fix-to-navaid distance and slant range distance must be considered. Such differences can be significant within 45 miles of the navaid. Figure 4-9 shows a comparison of an 11-mile DME (slant range) fix and the actual fix-to-navaid distance and points out the required comparison when plotting airspace to be protected. For simplification, differences of 1/4 miles below 14,000 and 1/2 mile at and above 14,000 may be disregarded.

300 cps, and since the overall bandwidth was 20 mc, there were 66,666 different frequencies. The matched filter is tuned to react to only half of the overall bandwidth, so the filter will receive only 33,333 different frequencies. This is in turn covered in 10 different steps by the 10 filters, so each individual filter will receive only 3,333 different frequencies. For ease of explanation, only 3,300 frequencies will be used in the remainder of this chapter.

EFFECT OF A TUNED AMPLIFIER ON FREQUENCIES WITHIN ITS BANDWIDTH. —In a paralleled resonant tank circuit the voltage and current are in phase at f_o. At frequencies below f_o, the circuit appears inductive X_L, and voltage leads the current. The farther below f_o the frequency is, the more inductive the tank appears, and the greater lead voltage has over current. At f_1, the voltage leads the current a maximum usable amount.

1078

AC.10

Figure 4-9.—Fix-to-navaid distance and slant range distance.

Additionally, the no-course signal zone associated with TACAN and VOR navaids must be kept in mind when establishing DME holding fixes.

A graph included as an appendix to Handbook 7130.3 has been established for the purpose of determining both fix-to-navaid and slant range distance and whether a particular fix falls within the no-course-signal zone.

By use of DME as a holding fix, the holding may be accomplished either toward or away from the primary navaid. When holding toward the navaid, the fix end of the holding pattern airspace may lie within the no-course-signal zone, provided that normal pattern entry is from a direction other than through the no-course-signal zone. When holding away from the navaid, no part of the holding pattern airspace may lie within the no-course-signal zone. (See fig. 4-10.)

To substantiate the reasoning of the preceding paragraph, imagine an aircraft holding in each situation pictured in figure 4-10. When holding away from the navaid, at the completion of the outbound leg of the holding pattern, the pilot must turn to proceed inbound to the holding fix on a specified radial. Since no bearing (radial) information is available in the no-course-signal zone, the complete pattern must be one in which bearing information is available. Compare this to holding toward the navaid. When the pilot reaches the holding fix, which must be outside the no-course-signal zone, he will turn to proceed outbound on a heading to parallel the inbound course. Positive course guidance is not necessary for proper execution of this portion of the holding pattern. Therefore, a portion of this type holding pattern airspace area may fall within the no-course-signal zone.

OPTIONAL REDUCTION AREAS

Figure 4-11 is an example of template No. 9. Depicted are the fix end and outbound

AC.11

Figure 4-10.—DME holding.

10806

AC.12

Figure 4-11.—(A) Holding pattern template; (B) area of entry.

end reduction areas shown by dotted lines. For more efficient use of available airspace, these reduction areas may not have to be considered when providing protected airspace if certain conditions exist.

For example, the fix end reduction area may not have to be included if entry into the holding pattern is made from a direction that lies within the crosshatched area depicted in figure 4-11 (B) as the area of entry. Additionally, a table has been established and is included as an appendix to Handbook 7130.3 which shows the various DME holding pattern leg lengths which may be used and the outbound end reduction areas which must be included for a particular fix-to-navaid versus template number situation. This table must be referred to when establishing a DME holding pattern and the associated protected airspace.

APPLICATION OF HOLDING AIRSPACE FOR OBSTRUCTION CLEARANCE REQUIREMENTS

When determining minimum holding altitudes, the appropriate template selected for use in determining the holding pattern airspace area to be protected is also the primary area to be considered for obstruction clearance. In addition, a secondary area 2 miles wide surrounds the perimeter of the primary area and must be considered. Required obstruction clearance is contained in the TERP's handbook.

10807

CHAPTER 5

AIR TRAFFIC CONTROL

Naval shore activities which perform air traffic control functions use the procedures published in the Terminal Air Traffic Control Handbook 7110.8 (Series). This publication contains common civil/military air traffic control procedures agreed upon by the Department of Defense and the Federal Aviation Administration. In areas where a common procedure was not feasible, special military procedures were specified in the handbook and so marked to indicate applicability. Additionally, the provisions of OpNav Instruction 3710.7 (Series) apply to naval ATC facilities.

AIRPORT TRAFFIC CONTROL

All aircraft movement on the airport movement area and within the airport traffic area is normally governed by positive control requiring specific clearances from the control tower. Exceptions to this occur where preventive control has been authorized at facilities.

The following paragraphs in this section concern areas of interest normally encountered by senior AC's as supervisors. For more detailed study of basic airport traffic control, refer to the applicable section of the Terminal ATC Handbook 7110.8 (Series) or Air Controlman 3 & 2, NavPers 10367-D.

LOCAL AIR TRAFFIC OPERATIONS

A continuous review of local VFR traffic operations is necessary to insure that traffic patterns and arrival and departure corridors are established to provide maximum avoidance of populated areas and established airways or routes. For a smooth operation, adequate coordination and cooperation must be maintained with adjacent airfields and the appropriate FAA authorities.

Airport information contained in the various publications and training programs must be sufficient to allow pilots and air traffic control personnel to become thoroughly familiar with the regulations concerning the facility.

Control Tower

The control tower exercises control of all air and vehicle traffic on and around the airport, and all such movements must have prior approval from the tower. Senior AC's in supervisory positions must insure that tower personnel are thoroughly indoctrinated concerning their responsibilities and the use of proper techniques, phraseology, and control procedures.

Formation Takeoffs and Landings

A formation is a flight of more than one aircraft operating by prior arrangement as a single aircraft with regard to altitude, navigation and position reporting, and where responsibility for separation between aircraft within the flight rests with the pilots in that flight.

Formation flying is authorized only for those units and types of aircraft for which a valid requirement exists. Appropriate commanders must insure issuance of and adherence to specific instructions and standard operating procedures for all aspects of formation flying since it is contrary to the procedures prescribed in TATC Handbook 7110.8 (Series).

Two-plane section takeoffs for aircraft of similar performance may be authorized for units and types of aircraft whose military missions require such for essential pilot training. Maximum lateral separation should be maintained with the leading aircraft on the downwind side, where applicable, during formation takeoffs.

10808
V0801

When a landing interval will result in two or more aircraft on the runway at the same time, staggered landings on alternate sides of the runway should be made. When crosswind conditions dictate, or when centerline landings are preferred, the landing interval would be the same as that for aircraft operating independently.

Crash and Firefighting Equipment

Firefighting, crash, rescue, and ambulance equipment at air activities must be alerted and in an efficient operating condition while flight operations are in progress. During such operations, appropriate equipment should be stationed at strategic locations on the field. In the event an emergency is anticipated, the various types of equipment should be relocated, depending upon their particular mission, to the best possible position in relation to the anticipated scene of the emergency.

Although ATC personnel are not responsible for the placement of such equipment, collaboration and coordination is necessary with the Crash Captain and his assistants to provide for the best possible response to an emergency on the airport movement area.

More detailed information concerning crash and firefighting equipment and procedures useful to a supervisor may be found in NavPers 10367-D, AC 3 & 2.

Control Tower Nonvisibility Areas

Where portions of the airport surface or traffic pattern are not visible from the tower, supervisory personnel must insure that such information is given appropriate dissemination to those concerned. A description of such areas should be developed, both for printed and oral use, of sufficient detail to insure understanding of the discretionary use of such areas and the reasons therefor.

Intersection Takeoffs

At facilities where intersection takeoffs are authorized, supervisory personnel must insure that appropriate distance information is available to controllers concerning the amount of usable runway available beyond an intersection. An airport diagram showing such information should be constructed and made available to controllers.

CONTROL TOWER VISIBILITY OBSERVATIONS

The following paragraph is adapted from the Federal Meteorological Handbook No. 1, Surface Observations, NavAir 50-1D-1.

Unless otherwise exempted, certificated, qualified Navy Air Controlmen, or otherwise authorized tower personnel, must report prevailing visibility when the prevailing visibility at the usual point of observation or at the tower level is less than 4 miles. These control tower visibility observations may be used immediately for aircraft operations but they must be recorded and forwarded to the weather station as soon as practicable. During this condition, control tower personnel must notify the weather station as soon as possible when they observe the prevailing visibility at the tower level to decrease to less than 4 miles, and change by one or more reportable values. When the tower visibility is reported as variable, subsequent actual observed values within the limits of the reported variability need not be transmitted to the weather station.

NOTE: For a review of prevailing visibility, variable visibility, and reportable values, refer to AC 3 & 2, NavPers 10367-D, chapter 5.

Where control tower visibility observations are required of controllers, visibility charts identifying lights or objects used in determining visibility at the station should be maintained in the tower. Separate charts for day and night use may be maintained; otherwise, one chart with an indication of each marker's day or night use should be prepared. The charts should incorporate features for easy identification of markers and distance determination. Coordination with weather service personnel is necessary to produce an appropriate visibility chart.

Dark or nearly dark objects outlined against the horizon sky are preferred as markers for daytime visibility evaluations. However, the use of less ideal markers is usually necessary in order to obtain a representative value for each sector.

The most suitable objects for determining visibility at night are unfocused lights of

0180H0809

moderate intensity at known distances. The red or green "course lights" of certain airport beacons; TV and radio tower obstruction lights, etc., may be used as definite nighttime visibility markers. Because of their intensity, focused lights, such as the airport beacon, may not be used as visibility markers. However, the degree of their brilliance may be used as an aid to indicate whether the visibility is greater or less than the distance to the light source. Before taking a visibility observation at night, the observer should spend as much preliminary time in a darkened or dimly lighted area as practicable, to allow for accommodation of his eyes to the darkness.

At stations where the visibility must be determined over short distances (less than 7 miles) and the absence of appropriate visibility markers requires estimates, values greater than the distance for which markers are available will be estimated. Under such conditions, visibility values greater than 7 miles will not be reported.

To estimate the visibility when it is greater than the distance to the farthest marker, the sharpness with which the marker stands out should be noted. Sharp outlines in relief with little or no blurring of color indicate that the visibility is much greater than the distance to the reference object. A blurred or indistinct object indicates the presence of an obstruction to vision that has reduced the visibility to not much more than the distance to the object.

Runway Visibility and Visual Range

Runway visibility value (RVV) is the visibility along a runway in terms of the distance a moderate intensity light source can be seen. Runway visual range (RVR) represents the horizontal distance a pilot will see down a runway from the approach end in terms of the distance high intensity runway lights can be seen. RVR is replacing RVV because it is a more realistic and accurate indication of what the pilot will encounter when on the runway. Its primary advantage is that it takes into account the penetrating capability of the high intensity runway lights (HIRL).

The presentation of RVV or RVR for use by controllers is through a meter display calibrated in fractions of a mile for RVV or a digital display calibrated in feet for RVR. These readout display instruments are normally located in the weather service office, the RATCC, and the control tower.

If available, RVV or RVR may be used concerning the visibility minimum for an IFR departure or or an approach (except circling approaches) in lieu of the prevailing visibility.

IFR PROCEDURE FOR AIR TRAFFIC CONTROL

The purpose of naval air stations is to support aircraft operations. In order to perform this function it is essential that these airfields are equipped with navaids and communications equipment and can provide services necessary to control aircraft operating under IFR conditions.

Naval air stations are categorized based upon equipment and services available from the following list:

1. Crash/rescue equipment.
2. Hard surfaced runway with standard runway markings.
3. Runway lights.
4. Control tower.
5. UHF air-ground communications.
6. Flight planning facilities (including weather briefing and NOTAM services).
7. Published instrument approach procedure (other than radar).
8. Approach control service.
9. Air surveillance radar.
10. Precision approach radar.
11. High intensity runway lights (HIRL).
12. Approach lights, U.S. standard A (or equivalent).
13. Runway centerline lights.
14. Touchdown zone (TDZ) lights.
15. Runway visual range (RVR) capability.
16. Radar equipped terminal area facility.

CNO will categorize air stations initially using the information in the DOD FLIP IFR SUPPLEMENT. The following defines airfield category in terms of IFR capability and the required equipment and service:

CATEGORY A—Precision Approach (PAR, ILS, AWCLS) with minimums less than 100 feet height above terrain (HAT) and 1/4 mile visibility (1,200 feet RVR) and all the equipment and services listed in the previous list.

10810

CATEGORY B—Precision approach with minimums less than 200 feet HAT and visibility 1/2 mile (2,400 feet) but not less than 100 feet HAT and visibility 1/4 mile (1,200 feet RVR), and the equipment and services numbered 1 through 12 of the previous list.

CATEGORY C—Precision approach with minimums not less than 200 feet HAT and visibility 1/2 mile (2,400 feet RVR), and the equipment and services numbered 1 through 11 of the previous list.

CATEGORY D—Nonprecision approach (TACAN, ADF, VOR) and equipment and services numbered 1 through 8 of the previous list.

Certainly a major part of the overall capability must depend upon the ability of controller personnel to expeditiously apply separation criteria to the control of IFR traffic. The term approach control includes this application and encompasses both arriving and departing aircraft. Local policies, agreements, training programs, and mission requirements definitely have an effect on controller procedure at a particular facility. The procedures listed herein are considered applicable to facilities in general.

IFR CLEARANCE

A clearance is defined as authorization by air traffic control, for the purpose of preventing collision between known aircraft, for an aircraft to proceed under specified traffic conditions within controlled airspace. An IFR clearance, then, is authorization as described above to operate in accordance with the instrument flight rules. An IFR clearance is normally issued by an ARTCC in whose area an IFR flight originates. However, at approach control locations, the initial/final portion of the clearance may be a mutually agreed departure/arrival clearance that meets separation requirements of the ARTCC and the terminal facility. Under certain conditions, such as a proposed flight to be conducted entirely within the terminal facility's area of responsibility, the terminal facility will issue the IFR clearance. Such procedures, as with the procedures for the issuance of short range clearances, are established and published locally in the appropriate format—usually Letters of Agreement.

An IFR clearance can be very simple or quite complicated, depending on traffic conditions and operations authorized by the clearance. Each clearance will contain all or part of the following items, as appropriate, in the order listed:

1. Aircraft identification.
2. Clearance limit or approach clearance.
3. Route of flight.
4. Altitude data in the order flown.
5. Departure procedure or SID.
6. Holding instructions.
7. Any special information.
8. Frequency and beacon code information.

Route or Altitude Amendments

When the route of flight in a previously issued IFR clearance requires amending, one of the following methods must be used:

1. State which portion of the route is being amended and then state the amendment.

EXAMPLE: CHANGE VICTOR TWENTY TWO TO READ VICTOR TWO TWENTY. (Only route in the clearance.)

2. State the amendment to the route and then state that the rest of the route is unchanged.

EXAMPLE: CHANGE J TEN TO READ J TWENTY, REST OF ROUTE UNCHANGED.

3. Reissue the entire route, including the amended portion in the appropriate place.

When a route or altitude in a previously issued clearance is amended, all applicable altitude restrictions must be restated or state that the restrictions are cancelled.

Composite Flight Plan

The clearance limit for an IFR proposal planning IFR operations for the initial part of the flight and VFR operations for the latter part would be the fix at which the IFR portion ends.

A proposal planning VFR for the initial part of the flight and IFR for the latter part of the flight is treated as a VFR departure. IFR clearance would be issued when the pilot requests it, approaching the fix where he proposed to start IFR operations. The remainder of the flight would simply be treated as any other IFR flight.

81801 10811

COORDINATION BETWEEN FACILITIES

•For efficient operation, constant coordination is necessary between ATC facilities. The content and the scope of information exchanged between facilities differ, depending upon the type of ATC service provided.

IFR flight progress data is forwarded from controller to controller within and between Centers and terminal facilities when operating in an en route capacity, as aircraft progress along a route. Such information must be forwarded at least 15 minutes before the aircraft concerned is estimated to enter a receiving facility's area. In such cases the information forwarded is as follows:

1. Aircraft identification.
2. Type of aircraft and appropriate equipment suffix.
3. Assigned altitude/FL and ETA over the last reporting point/fix in the transferring facility's area or assumed departure time when the departure point is the last point/fix in the transferring facility's area.
4. Altitude/FL at which the aircraft will enter the receiving facility's area if other than the assigned altitude.
5. True airspeed.
6. Point of departure.
7. Route of flight remaining.
8. Destination airport and clearance limit if other than the destination airport.
9. ETA at destination airport if other than military or scheduled air carrier aircraft.
10. FL requested by the pilot of a turbojet aircraft, if assigned FL differs from the requested FL (within a facility only).
11. Longitudinal separation being used between aircraft at the same altitude, if it results in the aircraft having less than 10 minutes separation at the facility's boundaries.

The position report over the last reporting point in the transferring facility's area should be forwarded to the receiving facility if any of the following conditions exists:

1. The time differs by more than 3 minutes from the estimate previously forwarded.
2. It is requested by the receiving facility.
3. It is agreed to, between facilities, as a routine operation.

When necessary to revise information already forwarded, the revised information is forwarded as required except that revision to the ETA over the last fix in the transferring facility's area is required only if it differs by more than 3 minutes from the estimate already given.

Centers forward the following information to approach control facilities before transfer of control jurisdiction. NOTE: Transfer points are usually specified in a Letter of Agreement.

1. Aircraft identification.
2. Type of aircraft and appropriate equipment suffix.
3. ETA or actual time, and proposed or actual altitute of the clearance limit. The ETA need not be given if the arrival information is being forwarded during a radar handoff.
4. EAC issued the aircraft.
5. Time, fix, or altitude when control responsibility is transferred to the approach control facility.

Approach control facilities must keep ARTCC's currently advised of the following information:

1. The particular approach that may be expected, where two or more instrument approach procedures are published or the fact that radar vectors to the traffic pattern will be used.
2. Highest altitude in use by the approach control facility at the holding fix.
3. Average time interval between successive approaches.
4. Arrival time of aircraft over the holding fix or a statement or other indication that acknowledges control responsibility if already received.
5. Revised EAC if different by 10 minutes or more from that issued by the ARTCC. (The ARTCC may issue EAC's to arrivals; however, this operation is usually covered in a Letter of Agreement.)
6. Missed approaches if they affect the ARTCC's area of operation.

The facility providing IFR service to the terminal area must forward the following information to nonapproach control towers soon enough to allow adjustment of the traffic flow, or to FSS's soon enough to allow provision of airport advisory service (the specific time

10812

requirement is usually covered in a Letter of Agreement):

1. Aircraft identification.
2. Type of aircraft.
3. ETA and proposed altitude over the fix.
4. Type of instrument approach procedure the aircraft will execute.

Nonapproach control towers must forward the following information to the ARTCC or approach control as appropriate:

1. When an arriving aircraft is sighted and, in the tower controller's judgment, a landing can be completed.
2. Actual time of arrival.
3. Pilot report of cancellation of the IFR flight plan.
4. Information related to missed approach aircraft or overdue/unreported aircraft.
5. Runway in use.

DEPARTURE PROCEDURE

Departure control is an approach control function responsible for insuring separation between departures. Departure control may suggest a takeoff direction other than that which may normally have been used so as to expedite the handling of departures. At times it is preferred to offer a pilot a runway that will require the fewest turns after takeoff to place his aircraft on the filed course or selected departure route as quickly as possible. At some locations a runway use program may be in effect which pays particular attention to noise abatement programs and will route departures away from congested areas.

IFR Clearance for Departing Aircraft

The departure clearance is issued before takeoff and should include the following items as applicable:

1. Clearance limit. This should be the destination airport when practicable even though it may be outside of controlled airspace. Where authorized and prescribed, short range clearances may be used which would necessarily specify some fix other than the destination as the clearance limit.

2. Route of flight. When assigning a route of flight, an aircraft should be cleared via esablished airways, route structures, and navaids established for the altitude stratum in which the operation is to be conducted. Routes through uncontrolled airspace should be included only when requested by the pilot.

When any part of an airway or route requested is unusable because of navaid status, aircraft should be cleared via one of the following alternative routes:

a. A route published in the AIM and depicted on U.S. Government charts. The word SUBSTITUTE should be used immediately preceding the alternative route in issuing such a clearance.

b. A route defined by specifying navaid radials or courses.

c. A route defined as direct to or between navaids.

To effect transition within or between route structures, aircraft should be cleared via one or more of the following methods, based on VOR, VORTAC, or TACAN navaids (unless use of other navaids is essential to aircraft operation or ATC efficiency):

a. The aircraft should be vectored to or from the radials or courses of the airway or route assigned.

b. An SID should be assigned.

c. Aircraft may be cleared to climb via radials or courses of the airways or jet route assigned.

d. Aircraft may be cleared via direct to or between the navaids forming the airway or route assigned.

e. Aircraft may be cleared to climb on specified radials or courses of navaids.

If the aircraft will operate in an area adjacent to restricted airspace, the following action is required:

a. For joint-use or military climb corridor restricted airspace, coordinate as necessary with the facility designated as controlling facility or using agency and obtain permission for the aircraft to transit the airspace. If permission is not obtained, clear the aircraft so that it avoids the restricted airspace.

b. For prohibited or nonjoint-use restricted airspace, clear the aircraft so that it avoids the airspace unless the pilot informs you

10813

that he has obtained permission from the using agency to operate in the airspace or the using agency informs you that they have given the pilot permission to operate in the airspace, or unless the aircraft is on an approved altitude reservation flight plan.

Except when a pilot requests a detailed clearance or when military operations are conducted in an altitude reservation; operations are conducted above FL 600; or operations requiring special handling are conducted; an abbreviated departure clearance may be issued if its use reduces verbiage and the following conditions are met:

a. The route of flight filed with ATC has not been changed by the pilot or operations officer prior to departure.

b. The terminal facility is provided sufficient information about the flight to exercise its control responsibility.

c. Destination airport information is relayed between facilities concerned, prior to departure.

d. The assigned en route altitude is stated in the clearance.

The destination airport is not stated in the abbreviated departure clearance. When a specific SID, including a transition, is filed by the pilot, it is considered as part of the route of flight.

When no changes are required to the filed SID or route the phrase CLEARED AS FILED may be stated. An SID may be assigned by the controller if appropriate and any additional instructions or information necessary may be included along with the en route altitude.

When a filed SID or route will require minor revisions the same procedures applies except that the necessary revisions must be specified. Example: CLEARED AS FILED EXCEPT CHANGE DEPARTURE TO READ DUTCH ONE DEPARTURE, MAINTAIN FLIGHT LEVEL THREE FIVE ZERO.

In a nonradar environment, one, two, or more fixes as necessary to identify the initial route of flight must be specified.

3. Altitude. When assigning altitudes for an en route operation, aircraft should be cleared at altitudes or flight levels appropriate to the direction of flight. These altitudes/FL's are contained in FAR's and in AC 3 & 2, NavPers 10367-D. When traffic, meteorological conditions, or aircraft operational limitations prevent assignment of altitudes/FL's appropriate to the direction of flight, any cardinal altitude or flight level below FL 290, or any odd cardinal FL at or above 290, may be assigned without regard to direction of flight as follows:

a. For traffic conditions, this action may be taken only if one of the following conditions exists:

(1) The aircraft will remain within the facility's area and prior approval is obtained from other affected positions or sectors or the operations have been covered in a Facility Directive.

(2) The aircraft will proceed beyond the facility's area and specific operations and procedures permitting random altitude assignments are covered in a Letter of Agreement between the appropriate facilities.

(3) Military aircraft are operating on random routes and prior approval is obtained from the facility concerned.

b. For meteorological conditions, this action may be taken only if the controller obtains prior approval from other affected positions or sectors within the facility and, if necessary, from the adjacent facility concerned.

c. For aircraft operational limitations, this action may be taken only if the pilot informs the controller that the available appropriate altitude exceeds the operational limitations of his aircraft and only after prior approval is obtained from other affected positions or sectors within the facility and, if necessary, from the adjacent facility.

Consideration must be given to the atmospheric pressure and the lowest usable flight level when assigning FL's.

If practicable, the pilot should be informed when to expect climb or descent clearance or to request altitude change from another facility.

Aircraft must be cleared at an altitude at or above minimum en route altitude (MEA) or minimum crossing altitude (MCA) for any part of an airway or route within the originating facility's area and the first part of the airway or route into an adjacent facility's area except where one of the following applies:

a. An aircraft may be cleared below the MEA but not below the minimum obstruction clearance altitude (MOCA) if the altitude assigned is at least 300 feet above the floor of

81801 10814

controlled airspace and further provided that the following conditions are met:

(1) Nonradar procedures are used only within 22 miles of a VORTAC, CORTAC, or TACAN.

(2) Radar procedures are used only when definite operational benefits will be realized and the aircraft is vectored, and lost communications procedures are issued.

b. An aircraft may be cleared to operate on jet route below the MEA (but) not below the prescribed minimum safe altitude or above the maximum authorized altitude if, in either case, radar service is provided.

NOTE: Minimum en route and maximum authorized altitudes for certain jet route segments have been established above the floor of the jet route structure due to limitations on navigational signal coverage.

c. Where a higher altitude is required because of an MEA (and no MCA is specified), an aircraft must be cleared to begin climb to the new MEA immediately after passing the fix beyond which the new MEA applies.

d. Where MEA's have not been established, aircraft may be cleared at or above the minimum safe altitude prescribed in FAR.

When issuing an altitude or FL to be maintained en route, one of the following procedures should be used in the order of preference listed:

a. The altitude filed by the pilot should be assigned.

b. An altitude within the highest route stratum filed by the pilot and as near as possible to the altitude filed should be assigned.

c. An altitude as near as possible to the highest route stratum filed by the pilot should be assigned, and the pilot should be informed when or at what point he can expect clearance to an altitude within the stratum he requested. In this case the expected altitude should be as near as possible to that filed by the pilot originally.

4. SID routes. An SID may be assigned to air carrier or military aircraft whenever appropriate and to other aircraft only if the pilot requests it. If it is necessary to assign a crossing altitude which differs from the SID altitude, the changed altitude should be repeated to the pilot for emphasis. Some SID's do not include altitudes in the design, in which case the appropriate altitude to be maintained must be inserted in the proper place in the SID assignment.

5. Nonstandard departure routes. For departures from airports that provide airport traffic control service, the direction of takeoff, the direction of turn after takeoff, or the initial heading to be flown after takeoff may be specified. At airports without airport traffic control service the initial heading to be flown after takeoff may be specified when considered necessary. In such cases, the specification can only be made after the direction of takeoff and/or direction of turn after takeoff has been determined by coordination with the pilot.

6. Departing USAF/USN IFR flights must be instructed to read back the ATC clearance to insure receipt as issued.

7. Frequency and beacon code changes. Departing IFR military turbojet aircraft (except cargo and transport type) should be instructed to change to departure control frequency before takeoff.

If the local control position in the tower has override capability on the departure frequency, instruction to change to departure control frequency is included in the takeoff clearance. This allows the local controller to communicate with the aircraft if necessary on the departure control frequency. If the local controller does not have override capability, the same procedure is used; however, the pilot must be instructed to monitor guard channel to provide for communications with the local controller if necessary.

If the appropriate mode/code and departure control frequency have not been previously assigned, these items are included in the takeoff clearance.

Caution must be exercised so as not to require radiofrequency or beacon changes for turbojet aircraft before the aircraft reaches 2,500 feet above the surface.

Coordination With the Receiving Facility

If the departure point is less than 15 minutes flying time from the transferring facility's boundary, coordination with the receiving facility must be accomplished before takeoff of a departing aircraft. Facilities needing earlier

a180810815

To frequencies above f_o, the circuit will appear capacitive by the amount that the frequencies differ from f_o. Above f_o, the current leads the voltage by the amount of X_C to the frequency applied. At f_2, the current leads the voltage by the maximum usable amount. Since each tank circuit in the matched filter has a bandwidth of 1 megacycle, and receives 3,300 different frequencies, approximately 1,650 of them will be above f_o, and 1,650 will be below f_o. To those above, the tank will appear capacitive. To those below, it will appear inductive. To the one frequency at f_o the tank circuit appears purely resistive.

The tuned amplifier is so designed that signal voltages are coupled out rather than signal current. To determine which signal voltages will be developed by the tank, first a reference must be used. This reference is the voltage and current which occur at f_o of the tank, and which are in phase because the tank is resistive.

The 1,650 frequencies, both above and below f_o, are applied to the tank circuit (tuned amplifier) at the same time. The voltage at the frequency f_1 of the tank will be leading the f_o current by the amount of X_L that this frequency sees.

Frequencies in between f_1 and f_o will be leading by a lesser amount because the tank circuit will appear less inductive to these frequencies. These voltages will have been advanced in phase (or time) in respect to the voltage at f_o of the tank.

The voltage of the frequency f_2 will be retarded in phase (or time) because the tank circuit will appear capacitive to that frequency. Before any voltage can be developed, current had to first begin to flow (because current leads voltage across a capacitive circuit). Voltages at frequencies in between f_2 and f_o saw less X_C, therefore, were retarded less.

The output from this tuned amplifier will be a series of signal voltages at 3,300 different frequencies with the lowest frequency (f_1) occurring first because it was advanced the most in time, and the highest frequency (f_2) occurring last because it was retarded the most in time.

The Q of the tank circuit will be selected so as to advance the voltage at f_1 by 0.5-μsec, and to delay or retard the voltage at f_2 by 0.5-μsec. THE TIME DIFFERENCE BETWEEN THE TIME WHEN THE FREQUENCY AT F_1 IS DEVELOPED AND THE TIME WHEN THE FREQUENCY AT F_2 IS DEVELOPED WOULD THEN BE 1-μsec. Since there are 3,300 different frequencies produced and coupled out of the tuned amplifier in a period of 1-μsec, the time delay between each of these different frequencies is 0.00031 μsec. As shown in figure 15-18, the first frequency to leave the tuned amplifier would be the frequency at f_1, and each 0.00031 μsec thereafter another frequency would be developed and coupled out until the frequency of f_2 is developed 1 full μsec later.

Since frequency is the reciprocal of time, it can be seen that the output from each channel (1 μsec in time) will be 1 mc wide in frequency.

What has been done is to take 3,300 different frequencies, each one in phase, and time delay or time advance each one by a different amount. This process has created a waveform which begins to appear as a linearly swept FM wave, and is called time dispersion or phase dispersion.

COMBINED OUTPUT OF THE MATCHED FILTER. —As shown in figure 15-16, the entire frequency spectrum is applied to the input of each of the 10 filter channels simultaneously, but through a delay line for channels 2 through 10. This means that channel 1 will receive its input at the instant the spectrum is applied to the input of the filter; however, channel 2 will not receive its input until later in time due to

Figure 15-18. —Individual channel frequency output (expansion).

1080
1079

coordination may enter into agreement to establish this coordination. However, when agreements establish mandatory radar handoff procedures, coordination need only be effected in a timely manner prior to transfer of control.

The actual departure time must be forwarded to the receiving facility for departures that require advance coordination unless an assumed departure time is agreed upon and that time is within 3 minutes of the actual departure time.

Radar Departures

Departure control utilizing radar will clear aircraft out of terminal areas using standard instrument departures via radio navigation aids whenever possible, to reduce the amount of necessary coordination between facilities. Radar departures may be provided to expedite departures and to establish them on course by the most direct route. Radar departures may overlie but should not be restricted to the standard departure routes for radar or lost communications backup.

If a departure is to be vectored immediately after takeoff, the initial heading to be flown must be issued before takeoff. Additionally, it may be necessary to instruct the pilot to squawk low if a beacon reply is required immediately after takeoff.

Departing IFR aircraft may be vectored before reaching minimum vectoring altitude, provided that they are within 40 miles of the antenna site and a minimum of 3 miles separation is maintained from prominent obstructions shown on the radarscope. If the takeoff path is less than 3 miles from such obstructions, the vectors provided must increase the separation to 3 miles.

HOLDING PROCEDURE

Holding is a predetermined maneuver which keeps an aircraft within a specified airspace while awaiting further clearance. A holding fix is used as a reference point in establishing and maintaining the position of the aircraft while holding. Most generally used holding patterns are charted on en route high/low and area aeronautical charts.

Holding Instructions

General holding instructions include the following items:

1. Direction of holding from the fix.
2. Name or description of the holding fix.
3. Radial, course, bearing, airway, or jet route on which the aircraft is to hold.
4. Outbound leg length in miles if DME is to be used.
5. Direction of holding pattern turns, if left turns are to be made. (Right turns are standard.)

Detailed holding instructions consist of the same items as general holding instructions, and in addition the outbound leg length in minutes or miles and the direction of holding pattern turns are always specified.

Delay Anticipated

If a delay is anticipated requiring an aircraft to be held and the holding pattern is not charted, the following items as appropriate must be issued at least 5 minutes before the aircraft is estimated to reach the clearance limit:

1. General holding instructions.
2. Detailed holding instructions if the pilot requests or the controller deems it necessary.
3. The time at which the pilot can expect to receive approach clearance (EAC) or further clearance (EFC).

If a delay is anticipated and the holding pattern is charted, the following items must be issued at least 5 minutes before the aircraft is estimated to reach the clearance limit:

1. Direction the pilot is to hold.
2. EAC or EFC.

NOTE: The direction issued must correspond to that charted unless another holding pattern is required for ATC purposes in which case it would be treated the same as any noncharted holding procedure.

Delay Not Anticipated

If it becomes apparent that an aircraft will not be delayed at a clearance limit and clearance beyond the clearance limit is required, the following action is required:

1. For departing or en route aircraft—clearance beyond the clearance limit must be

10816

issued at least 5 minutes before the aircraft reaches the clearance limit.

2. For arriving aircraft—clearance beyond the clearance limit must be issued before the aircraft reaches the clearance limit.

Clearance Beyond the Holding Fix

When issuing clearance beyond the holding fix, the following items should be included:

1. A clearance limit or approach clearance.
2. Route of flight. This should include complete details of the route, airway, course, heading, arc, or vector to be used. The phrase VIA LAST ROUTING CLEARED may be used only when the most recently issued routing beyond the holding fix can be reinstated and verbiage will be reduced.

Lengthy Delay

If it is determined that an aircraft intending to land within a facility's area of responsibility would be delayed more than 1 hour, the EAC or EFC should be issued as soon as practicable after such aircraft enter the facility's area and the aircraft operator or military equivalent notified.

Holding Patterns and NavAids

The holding pattern airspace is determined as described in chapter 4 of this manual. By requiring the pilot to keep his aircraft within the specified airspace and other aircraft out of the same airspace, separation is maintained.

Holding points are normally navaids; however, a location that the pilot can determine by visual reference or a visual holding point may be used. In such cases, the controller must determine that the pilot is familiar with the visual holding point.

When holding is accomplished by using unmonitored navaids as the holding fix, separation must be provided for any other aircraft that may occupy the course which the holding aircraft will follow in the event the holding aircraft does not receive signals from the unmonitored navaid.

ARRIVING AIRCRAFT

The initial clearance issued IFR aircraft will include, whenever practicable, the destination airport as the clearance limit. However, an ARTCC may clear an aircraft to a fix short of its destination airport and normally amends an existing destination airport clearance limit to a fix short of destination for the purpose of transfer of control responsibility of an en route aircraft to a terminal facility. In such cases, if no delay is anticipated, clearance beyond such clearance limit must be issued to arriving aircraft before the aircraft reaches the clearance limit. Transfer of radio communications and control responsibility must be accomplished soon enough to allow the receiving facility to issue further clearance before the aircraft reaches the clearance limit. Specific requirements for transfer of control of arriving aircraft are usually stated in a Letter of Agreement.

At nonapproach control locations the ARTCC retains control of arrivals until they have landed, canceled IFR, or until they are no longer a factor in provision of IFR service. At approach control locations the center normally clears all arriving IFR traffic to the appropriate holding point, and in some cases includes holding instructions and the expect-approach-clearance times in such clearance. The number of aircraft to be released to approach control by the center is determined by a joint center/approach control Letter of Agreement.

Advance Approach Information

When an aircraft intends to land at an airport where approach control service is provided and two or more instrument approach procedures are published, the facility controlling the aircraft immediately before entry into the approach control area should inform the pilot of the type of approach to expect or that he will be vectored to the traffic pattern. This information may be omitted if airport terminal information service (ATIS) is provided by the airport or if the visibility is 3 miles or better and the ceiling is at or above the highest initial approach altitude established for any low altitude instrument approach procedures for the airport.

Approach Control

Approach control is responsible for controlling all instrument flight operating within its area of responsibility. Approach control may serve one or more airports, and control is

81861 10817

exercised primarily by direct pilot/controller communications.

Approach control facilities must provide arriving aircraft with approach information on initial radio contact or as soon as possible thereafter. The approach information consists of the following:

1. Approach clearance or type of approach to be expected if two or more approaches are published and the clearance limit does not indicate which will be used.
2. Runway in use.
3. Surface wind.
4. Ceiling and visibility if the ceiling at the airport of intended landing is reported below 1,000 feet or below the highest circling minimum, whichever is greater, or the visibility is reported less than 3 miles. When such conditions exists, any known changes classified as special weather observations must also be transmitted as soon as the volume of traffic, controller workload, and communications frequency congestion permits.
5. Altimeter setting.

Specific items of approach information do not have to be reissued if the pilot indicates he has already received them via ATIS or the ARTCC.

Approach control service is provided at terminal facilities for the purpose of maintaining an orderly flow of arriving traffic without interruptions of continuity while expediting departures. The order in which arrivals are positioned while awaiting approach clearance or while on approach is termed the approach sequence. Many factors affect an approach sequence. The ARTCC has a considerable effect on the sequence by the altitude/FL assigned to aircraft released to approach control. The most desirable result is to prevent delays to arriving aircraft.

The time lapse between aircraft on approach or between expect-approach-clearance times issued is termed the approach interval. Again many factors affect the interval such as type of aircraft, type of approach, weather conditions, etc. Probably the most influential factor concerning the approach interval is the length of the approach procedure and the separation required between aircraft on approach. If only one aircraft may be on approach at one time, then the interval is the average time it takes to complete the approach. For two different approaches to the same runway, or possibly one approach, it is possible to have more than one aircraft in certain segments of approach at the same time provided appropriate separation is maintained.

Timed approaches appear to allow the shortest time interval under manual or nonradar type approach control procedure. Timed approaches are seldom used by naval facilities due to the wide variety of aircraft operational characteristics involved at such facilities. Timed approaches are most effective when used with aircraft of similar operating characteristics such as speed. If all conditions are perfect, it is possible to have an interval of 2 minutes between aircraft using timed approach procedures.

Each approach control operation maintains its operational identity, in that, it is adapted to a particular local traffic situation. However, it can be said that the desired results of approach control's concern with arriving aircraft are as follows:

1. Maintenance of an approach sequence that avoids gaps and unnecessary delays between approaches.
2. Use of the minimum possible approach interval, consistent with the appropriate separation required.

At nonapproach control locations, a subsequent arriving aircraft can only be cleared for an approach after one of the following conditions exists:

1. The preceding aircraft has landed or canceled IFR.
2. The preceding aircraft is visible to the tower controller at that location and, in his judgment, landing can be completed.

Nonradar Approaches

The order of priority of issuance of appraoch clearance is normally established on the basis that the first aircraft estimated over the fix from which approaches are commenced will be the first to receive an approach clearance, followed by other aircraft in the order of their estimated or actual times of arrival over the fixes. If visual contact with the ground is made before the approach is completed, it is required that the complete approach procedure be

10818

followed unless ATC has authorized a contact approach or the pilot cancels his IFR flight plan.

To require an aircraft to execute a particular instrument approach procedure, the controller must specify in the approach clearance the name of the approach as published on the approach chart.

If landing will be made on a runway other than that alined with the direction of instrument approach, instructions to circle to the runway in use must be included in the approach clearance.

When adherence to an altitude as published on the approach chart is required for separation from other aircraft, the altitude must be specified in the approach clearance.

If it is determined that a pilot is unfamiliar with an approach procedure, a complete description of the approach must be included in the approach clearance.

Clearance for a high altitude penetration may be issued in conjunction with a clearance for approach, a vector to a final approach course, or to a fix or altitude from which a clearance for an approach can be given when no delay is anticipated.

A military en route descent for trubojet aircraft may be authorized provided that only normal vectoring delays are anticipated. It may be used in a nonradar environment; however, radar capability should exist which will permit the aircraft to be vectored to the final approach course of a published high altitude instrument approach procedure or PAR/ASR approach. The type of final approach to be conducted must be mutually understood by the pilot and controller before the en route descent is begun. Prior to issuance of an en route descent clearance, the current weather conditions at the destination airport must be transmitted when any of the following conditions prevail:

1. The ceiling is below 1,000 feet.
2. The ceiling is below the highest circling minimum.
3. The visibility is below 3 miles.

To avoid requiring an aircraft to fly at low altitude for an excessive distance, descent clearance should be issued at a point determined by adding 10 to the first two digits of the flight level; for example FL 370; 37 plus 10 equals 47 miles.

A turbojet en route descent should not be terminated without the consent of the pilot except as required by a radar failure or an emergency situation. It remains the pilot's prerogative to elect to conduct a published high altitude penetration instead of an en route descent.

Clearance for a contact approach may be issued only if the following conditions are met:

1. The pilot requested it.
2. The reported ground visibility is at least 1 statute mile for all aircraft except civil air carriers which must have 1/2 statute mile. Approved separation must be applied between aircraft authorized to conduct a contact approach and other IFR and special VFR aircraft. When applying vertical separation, a fixed altitude should not be assigned; clear the aircraft at or below an altitude which is at least 1,000 feet below any other IFR traffic but not below the minimum safe altitude. An alternative clearance should be issued when weather conditions are such that a contact approach may be impracticable.

Radar Approach Control

In a radar environment, arriving aircraft may be cleared to an outer fix most appropriate to the route being flown with vertical separation and, if required, given holding instructions. When radar handoffs are effected between the ARTCC and approach control, or between two approach control facilities, aircraft are cleared to the airport or to a fix so located that the handoff will be completed prior to the time the aircraft reaches the fix. When radar handoffs are utilized, successive arriving flights may be handed off to approach control with radar separation in lieu of vertical separation, provided that such procedures are previously agreed upon between the facilities concerned and the following conditions are met:

1. The first aircraft communicates with the receiving facility before a second aircraft, cleared to or over the same fix, is told to communicate with the receiving facility. This need not be applied if the first aircraft is cleared to the airport.

10819

2. The first aircraft communicates with the receiving facility before it reaches the clearance limit fix.

3. The receiving facility does not delay or hold the first aircraft at the fix to or over which a second aircraft is cleared.

Radar vectors and altitudes/FL's will be assigned as required for spacing and separating aircraft. Aircraft will normally be informed when it is necessary to vector through the final approach course for spacing or other reasons. In the event the controller is unable to so inform the pilot, he is not expected to turn inbound on the final approach course unless approach clearance has been issued (such as for ILS, VOR, TACAN final approach).

Approach clearance will normally be issued with the final vector for interception of the final approach course, and the vector will be such as to enable the pilot to establish his aircraft on the final approach course prior to reaching the approach fix. This approach clearance would not be issued in the case of an ASR or PAR approach.

In addition to the foregoing conditions, if terrain or traffic does not permit unrestricted descent to the lowest published altitude specified in the approach procedure for which cleared, the controller must either defer issuance of approach clearance until there are no restrictions, or issue altitude restrictions with the approach clearance specifying when or at what point unrestricted descent can be made. Except for ASR/PAR, the pilot would have to be instructed to contact the tower or monitor a certain frequency until completion of the approach.

APPROACH SEPARATION RESPONSIBILITY.—When approaches are not monitored by the PAR controller, the radar approach controller must maintain radar separation until visual separation can be provided by the tower controller. The tower controller may provide radar separation within an area designated for his use if this responsibility has been delegated to him in a Letter of Agreement or Facility Directive.

When monitoring instrument approaches, the PAR controller must provide IFR separation between aircraft on approach from the final approach fix to the airport until visual separation is provided by the tower controller.

When timed approaches are being conducted, the radar controller must maintain radar separation until the aircraft is observed to have pased the final approach fix inbound and is within 5 miles of the runway on final approach course or until visual separation can be provided by the tower controller.

VISUAL APPROACH.—In a radar environment, ATC may descend an aircraft operating in accordance with an IFR clearance to the minimum vectoring altitude, vector it to the airport traffic pattern, and issue clearance for a visual approach. This may be done whenever the reported ceiling is at least 500 feet above the minimum vectoring altitude and the visibility is 3 miles or more.

With a visual approach, the pilot may deviate from the prescribed instrument approach procedures and proceed to the airport visually, maintaining VFR conditions at all times. This procedure affords a more expeditious service to arriving aircraft and precludes unnecessary vectoring to the final approach course of a published instrument approach.

Radar separation must be provided from any preceding IFR aircraft until visual separation can be provided. The radar controller must continue flight following and traffic information until the pilot is instruced to contact the tower. The point at which an aircraft cleared for a visual approach is instructed to contact the tower will vary, depending on the runway in use, weather, etc., and it is determined by prior coordination between the tower and approach control. Ordinarily, the changeover occurs at least 5 miles from the runway. Changeover points should be far enough from the airport so that the tower controller can properly establish a landing sequence but not at a distance which may derogate the provision of radar traffic information.

If an arriving aircraft is not following a preceding arriving aircraft sequenced by approach control, it may be cleared for a visual approach when the following conditions exist:

1. The pilot of the aircraft concerned reports sighting the airport.

2. The tower controller is informed of the aircraft's position.

If the aircraft concerned is following a preceding arriving IFR or VFR aircraft sequenced

10819 10820

by approach control, it may be cleared for a visual approach when the following exist:

1. The pilot of the succeeding aircraft reports sighting the preceding aircraft.
2. The tower controller is informed of the succeeding aircraft's position in the approach sequence.
3. The pilot of the succeeding aircraft is instructed to follow the preceding aircraft.

Aircraft may be vectored simultaneously to the traffic pattern for visual approaches to more than one runway or to the traffic pattern for visual approaches to one runway while aircraft are conducting a different type instrument approach to another runway provided that the applicable preceding conditional provisions for issuance of a visual approach clearance are adhered to and radar separation is maintained between IFR aircraft until at least one of the following conditions is met:

1. If parallel runways separated by less than 3,500 feet are in use, the pilot must have reported sighting the preceding IFR aircraft making an approach to the other runway and all aircraft involved must be informed that other arriving aircraft are using the other runway.
2. If parallel runways separated by 3,500 feet or more, or converging runways are in use, all aircraft involved must be informed that other arriving aircraft are using the other runway.

RADAR APPROACHES.—Prescribed or approved radar instrument approach procedures may be provided to any aircraft upon request and may be offered to aircraft in distress, regardless of weather conditions, or to expedite traffic.

The following information must be issued to aircraft that propose to conduct a radar approach:

1. Altimeter setting.
2. Ceiling and visibility if the ceiling is reported below 1,000 feet or below the highest circling minimum, whichever is greater, or if the visibility is less than 3 miles. When such conditions exist, all known changes which are classified as special weather observations must be transmitted as soon as the volume of traffic, controller workload, and communications frequency congestion permit.
3. Pertinent information on known field conditions if they are considered necessary to the safe operation of the aircraft concerned.
4. Lost communications procedures. When weather reports indicate an aircraft will likely encounter IFR weather conditions during the approach, lost communications instructions are issued as soon as possible after establishing radar identification and radio communications (this may be ommitted after the first approach when successive approaches are made and the instructions remain the same). Advise the pilot that if radio communications are lost for a specified time interval (not more than 1 minute) on vector to final approach, 15 seconds on a surveillance final approach, or 5 seconds on a precision final approach, one of the following actions should be taken:

a. Attempt contact on a secondary or tower frequency.
b. Proceed in accordance with VFR if possible.
c. Proceed with an approved nonradar approach.
d. Execute the specific lost communications procedure for the radar approach being used.

The pilot is responsible for determining the adequacy of lost communications procedures with respect to aircraft performance, equipment capability, or reported weather conditions. If a pilot should state that he cannot accept a lost communications procedure due to weather conditions or other reasons, the controller should request the pilot's intentions and take appropriate action.

If an aircraft on a radar approach proposes to execute a low approach or touch-and-go landing, climbout instructions including a specific heading and altitude must be issued before the aircraft commences final descent. If an aircraft is making a series of approaches, this type of instruction may be omitted after the first approach, provided that no change exists.

The pilot should be advised to perform cockpit check while the aircraft is on the downwind leg and in time to complete it before turning base leg. If an incomplete pattern is used, this instruction, must be issued prior to handoff to the final controller for a precision approach or prior to beginning descent on a surveillance approach.

10851 1080g

The following should be accomplished before the aircraft on a radar approach commences final descent:

1. Inform the pilot of the position of the aircraft at least once.
2. Inform the pilot of the type of approach (ASR or PAR), the runway to which the approach will be made, and, if appropriate, the airport.
3. Request the pilot to report wheels down and locked unless he has previously reported it.
4. Missed approach instructions should be issued according to the specific missed approach procedure approved for the radar approach in use.

A clearance must be obtained from the tower and relayed to the pilot for an aircraft on a radar approach to make a landing, touch-and-go, or low approach. Surface wind must be included with clearances for landing or touch-and-go. If such clearances are not received, the pilot should be informed and then issued instructions for an alternate course of action.

When directed by the control tower, instructions to execute a missed approach must be issued to the pilot of an aircraft on a radar approach. In such cases, or when the pilot initiates a missed approach, the missed approach should be monitored by the radar controller and advisories issued. Instructions that could be interpreted as a continuation of the approach must be avoided.

The pilot of an aircraft conducting a radar approach should be instructed to take over visually, execute the missed approach, or climb and maintain a specified altitude and fly a specified course, whenever the completion of a safe approach is questionable because one or more of the following conditions exists:

1. Safety limits are exceeded or radical target deviations are observed.
2. Position or identification of the aircraft is in doubt.
3. Radar contact is lost or a malfunctioning radar is suspected.
4. Field conditions or traffic preclude approach completion.

If radar contact is lost during an approach and the aircraft has not started on final approach, the aircraft should be cleared to an appropriate navaid for an instrument approach.

On a surveillance approach the controller provides navigational guidance in azimuth only. The pilot is furnished headings to fly to aline his aircraft with the extended centerline of the landing runway. Since the radar information used for a surveillance approach is considerably less precise than that used for a precision approach, the accuracy of the approach will not be as great and higher minimums will apply.

Guidance in elevation is not possible on a surveillance approach, but the pilot is given advance notice of where descent will begin, the straight-in minimum altitude/MDA for the approach, and instructions to begin descent when the aircraft reaches the descent point. Unless a descent restriction exists for the approach, the pilot is instructed to descend to minimum altitude/MDA at that point. If a restriction to the descent does exist, the prescribed restriction must be applied and the pilot is told to maintain a certain altitude until he is observed to have passed the altitude limiting point, after which he is instructed to descend to minimum altitude/MDA.

If recommended altitudes on final approach are requested by the pilot, they should be given down to the last mile which is at or above the published minimum altitude/MDA. The recommended altitudes are determined locally. For example, with a gradient of 300 feet per mile, add this value for each mile to the airport elevation and round it out to the nearest 100 feet.

The minimum altitude/MDA published for the approach procedure is applicable in determining the point at which recommended altitudes will be discontinued. For example, if the published MDA is 1,290 feet at an airport with an elevation of 970 feet MSL, altitude information is not given for the last mile because the recommended altitude of 1,270 feet would be below the MDA of 1,290 feet (300 plus 970 equals 1,270). Course guidance and the distance from the runway or touchdown (if using the azimuth portion of PAR) should be furnished the pilot each mile while the aircraft is on final approach. The pilot should be informed when his aircraft is on course and frequently informed when any deviation from the desired course is observed.

10822

published for the particular approach being executed or to be executed, a controller should take the following action:

1. Issue the weather report to each arriving IFR aircraft.
2. Request the pilot to state his intentions.
3. Issue approach clearance or other clearances or instructions as appropriate, according to the pilot's intentions and the traffic situation.
4. Qualify each landing clearance issued under these conditions with the phrase IF YOU HAVE LANDING MINIMUMS.

If the pilot of an arriving aircraft reports the weather conditions are below his landing minimums, a controller should take the following action:

1. Issue appropriate instructions to the aircraft to hold or proceed to another airport.
2. Adjust, as necessary, the position in the landing sequence of any other aircraft desiring to make approaches, and issue approach clearances accordingly.

Approach Monitoring

PAR equipment should be used to monitor approaches when the following conditions exists:

1. Whenever the reported weather is below basic VFR minimums.
2. When the navaid final approach course from the final approach fix to the runway coincides with the PAR final approach course.
3. When the final approach fix is within PAR coverage.

When approaches are being monitored, pilots of arriving aircraft should be informed of the frequency on which advisories will be transmitted if it will not be the same as the communications frequency used for the approach. No more than two aircraft or two flights of aircraft should be monitored simultaneously.

When issuing advisories, pilots should be informed when their aircraft are passing final approach fix. At that point the pilot may be instructed to report sighting the approach lights or the runway. The pilot should be advised if his aircraft is well left or right of course; and if conducting an ILS approach, he should be advised when well above or below the glidepath. If repeated advisories are issued and the aircraft is still proceeding outside the prescribed safety limits, the pilot should be advised to proceed visually or, if unable, to climb to a specified altitude and/or turn to a specific heading. Advisories may be terminated and the pilot concerned so informed when the pilot reports sighting the approach lights or the runway, or when the aircraft reaches the ILS middle marker or a point where the glidepath intercepts 200 feet elevation, whichever is nearer the landing threshold.

Practice Instrument Approaches

When requests for practice instrument approaches are received, controllers should take steps to determine the type of approach and how it will terminate, such as a touch-and-go, the missed approach maneuver, or a landing. When approving such requests, controllers should include instructions to conduct the entire approach in VFR conditions unless the aircraft is on an IFR flight plan and requests IFR separation. In addition, instructions are issued to report at a specific position for further clearance or abandon the approach.

Frequency and Beacon
Changes During Approaches

When military turbojet (except cargo and transport type) or A-1 type aircraft will conduct an instrument approach wholly or in part in IFR weather conditions or at night, an approach controller should take the following action:

1. Avoid radiofrequency and radar beacon changes to the maximum extent that communications capabilities and traffic conditions will permit. However, when changes are required, use the following procedures:

a. Instructions should be given early enough to allow the change before the aircraft reaches the approach fix or handoff point.
b. Frequency changes must be kept to a minimum below 2,500 feet above the surface and should be avoided during the time an aircraft is making a turn.

2. When the traffic volume requires, coordinate with the ARTCC and request that a frequency other than the one used by aircraft making approaches be used in transferring control of aircraft to the approach control facility.
3. A frequency common to both the GCA and approach control should be used for an approach, if practicable, to minimize frequency changes.

10824

4. When GCA is not able to communicate on a common frequency, a change to the GCA frequency may be authorized.

5. When a nonradar approach will be made, the pilot of the aircraft may be instructed to change to the tower frequency in the following instances:

a. The reported ceiling is at or above 1,500 feet and visibility is 5 statute miles or more.

b. The pilot reports that he is able to proceed by visual reference to the surface.

6. Radar beacon changes should be avoided after an aircraft begins a penetration/approach.

7. In the event of a missed approach, a frequency or beacon change should not be required before the aircraft reaches the missed approach altitude, MEA, or the minimum vectoring altitude.

Single Frequency Approaches

Where single frequency approach (SFA) procedures for single piloted turbojet aircraft on an IFR flight plan are contained in a Letter of Agreement, radiofrequency changes may not be required after the aircraft begins the penetration/approach, or after initial contact during an en route descent, until a landing or low approach has been completed, except under the following conditions:

1. During daylight hours while the aircraft is in VFR conditions.
2. On pilot request.
3. When the pilot cancels his IFR flight plan.
4. In an emergency situation.

Minimum Fuel

If a USAF, FAA, or USN jet aircraft declares a state of MINIMUM FUEL, a controller should inform any facility or controller to whom control jurisdiction is or will be passed of the minimum fuel situation. Facilities and/or controllers concerned must be alert for any occurrence which might delay the aircraft en route.

Use of the term MINIMUM FUEL indicates recognition by the pilot that his fuel supply has reached a state such that, upon reaching destination, he cannot accept any undue delay. This is not an emergency situation but merely an advisory that indicates an emergency situation is possible should any undue delay occur. Common sense and good judgment will determine the extent of special handling to be given in such situations.

10825

the delay line. Channel 3 will receive its input still later in time than channel 2. This process will continue so that channel 10 will receive its input last because the delay line in its input offers the largest amount of delay.

Channel 1, since it received the frequency spectrum first, will produce an output first. Channel 1 is tuned to 95.5 mc, and has a 1 megacycle bandwidth, so it will produce in its output only that part of the spectrum from 95 mc to 96 mc. The frequency to first appear at the output of channel 1 will be the lowest frequency within the bandwidth of the tuned amplifier. This is because the lowest frequency receives the greatest phase or time advance because of X_L of the tank circuit at that frequency. The last frequency to leave channel one will be the highest frequency within its bandwidth. This frequency receives the most time or phase delay because of X_C of the tank circuit to that frequency. Each of the remainder of the 3,300 frequencies will be either advanced or retarded by a lesser amount, so that the time required for channel 1 to reproduce all 3,300 frequencies will be 1 μsec.

As channel 1 is finishing its output waveform, channel 2 is just receiving the spectrum at its input (because the spectrum was delayed 1 μsec by the delay line). Channel 2 is resonant to 96.5 mc, has the same 1-mc bandwidth, and will reproduce that part of the spectrum from 96 mc to 97 mc. The lowest frequency within the bandwidth of channel 2 will be reproduced first because it receives the greatest advance by X_L. The highest frequency will be reproduced last because it is delayed by X_C. Channel 2 will require 1 μsec to produce its full 1-mc output. Two μsec in time have now elapsed.

As channel 2 finished producing its output, channel 3 receives the frequency spectrum at its input through the 2-μsec delay line. Channel 3 picks up in frequency where channel 2 left off and provides another 1-mc part of the output for a period of 1 μsec.

This process continues until channel 10 receives the frequency spectrum at its input after being delayed by the 9-μsec delay line. It then produces the tenth part of the total output waveform which is resonant from 104 mc to 105 mc. It is also 1 μsec wide.

The lowest frequency of channel 1 (95 mc) is produced, and 10 μsec later, the highest frequency of channel 10 (105 mc) is produced. This is shown in figure 15-19.

Each of the 10 channels output waveforms will be combined in the summing amplifier to produce the waveform shown in figure 15-19. This waveform sweeps a 10-mc band of frequencies during a time of 10 μsec with a linear change of 1 mc/1-μsec. This type of waveform is called a linear frequency modulated pulse. The matched filter which produces this type of waveform is called a LIFMOP filter being coined from LInear Frequency MOdulated Pulse. This LIFMOP waveform contains approximatedly 33,000 different frequencies, each one being in a very definite time and phase relationship to the others.

The output from each channel must be equal in amplitude. To insure equal amplitudes from each channel, an oscilloscope is connected to

Figure 15-19. —Summing amplifier output.

1080

CHAPTER 6

EMERGENCY PROCEDURES

Emergency procedures cannot always be prescribed for every situation which might be considered an emergency because of the infinite variety of possible situations. As a rule of thumb, an emergency includes any situation which places an aircraft in danger, uncertainty, alert, lost or distress. When it is believed that an emergency exists or is imminent, an air traffic controller must select and pursue a course of action which appears to be most appropriate under the existing circumstances. The decision as to what type of assistance is needed is based on requests and information received from the pilot, because he is authorized by FAR 91 to determine his course of action.

EMERGENCY ASSISTANCE

Maximum assistance must be provided aircraft in distress. This includes services of available radar facilities, military, FAA, and FCC DF facilities, and emergency services that may be available at or from these facilities.

If a controller is communicating with an aircraft in distress, he is the one who should handle the emergency and coordinate and direct the activities of assisting facilities. This responsibility should be transferred to another controller or facility only when it is determined that better handling of the emergency will result.

Information received about aircraft in distress should be forwarded in detail to the center in whose area the emergency exists, even VFR traffic. Logically this would mean en route traffic, not local traffic around your station. You may have to coordinate the efforts to assist any aircraft believed in distress either between facilities or between the aircraft and a facility.

Should your facility receive a request for information concerning an ALNOT from the tie-in FSS, a thorough search of the records is necessary to determine whether the aircraft has contacted or landed at your facility. No one can say which little piece of information may be the missing link or a key to the location of a downed aircraft.

A course of action determined appropriate for an emergency situation must be implemented as soon as enough information has been obtained to act upon. What is considered a minimum amount of information will naturally vary according to the situation; however, the following may be considered as a minimum for an inflight emergency:

1. Aircraft identification and type.
2. Weather, as reported by the pilot.
3. Nature of emergency.
4. Aircraft altitude/FL.
5. Pilot's desires.
6. Fuel remaining, in terms of time.

After initiating emergency assistance procedure, and if the nature of the situation allows, the following information is desirable and may be obtained from the pilot as necessary and as time permits:

1. Pilot capability for IFR flight.
2. Time and place of last known position.
3. Heading since last known position.
4. Airspeed.
5. Point of departure and destination.
6. Navaid equipment capability.
7. Navaid signals being rceived.
8. Visible landmarks.
9. Aircraft color.
10. Number of people on board.
11. Emergency equipment on board.

When providing emergency assistance, it may be best to keep the aircraft on the initial

10826 10829

contact frequency. Even though 121.5 and 243.0 MHz are available as emergency frequencies, their use is not mandatory. A frequency change for an aircraft in distress should be made only if there is a valid reason.

Aircraft orientation is of primary importance to the pilot of an aircraft that is lost or uncertain of his position. The initial phase of assistance to pilots in such situations will probably be some method of locating the aircraft such as radar, DF, navaids, landmarks, or sighting by other aircraft.

When considered necessary, and provided that the weather permits, a controller could recommend that the pilot maintain or increase altitude to improve communications, radar, or DF reception.

OVERDUE AIRCRAFT

An IFR aircraft is considered overdue when neither communications nor radar contact can be established with it and 30 minutes have passed after its ETA over a specified reporting point or clearance limit.

An aircraft on a combination VFR/IFR or air filed IFR flight plan is considered overdue when 30 minutes have passed since the pilot requested IFR clearance and neither communications nor radar contact can be established with it.

A VFR aircraft is considered overdue when communications cannot be established and it fails to arrive 30 minutes (15 munutes for jets) after its ETA.

EMERGENCY SITUATIONS

An emergency situation may be considered to exist, and the center should be notified immediately, when any of the following conditions exist:

1. An emergency is declared by either the pilot, facility personnel, or officials responsible for the operation of the aircraft.

2. Reports indicate that an aircraft has made a forced landing, is about to do so, or its operating efficiency is impaired to the extent that a forced landing will be necessary.

3. Reports indicate that the crew has abandoned or ditched the aircraft or is about to do so.

4. An emergency radar beacon (SIF) response is received on radar.

5. Intercept or escort aircraft services are required.

6. The need for ground rescue appears likely.

7. A left or right turn triangular pattern is observed on radar.

8. A series of four chaff drops followed by a series of 360° turns is observed on radar.

INFORMATION FORWARDED TO ARTCC

When an aircraft is considered to be overdue or in an emergency status, ARTCC must be alerted and forwarded the following information, as available:

1. Flight plan including the color of the aircraft if known.

2. Time of last transmission received, by whom, and the frequency used.

3. Last position report and how it was determined.

4. Action taken by the reporting facility and the proposed action.

5. Number of persons on board.

6. Fuel status.

7. Facility working the aircraft and the frequency being used.

8. Last known position, estimated present position, and maximum range of flight of the aircraft based on the remaining fuel on board and the airspeed.

9. Position of other aircraft near the distress aircraft's route of flight when requested.

10. Other information the controller deems pertinent.

Position Plots

The facility working the distress aircraft should plot the flight path of the aircraft on a chart, including position reports, predicted positions, possible range of flight, and any other pertinent information. The assistance of other aircraft known to be operating near the distress aircraft may be solicited. This information should also be forwarded to ARTCC.

8 80110827

RADIO COMMUNICATIONS FAILURE

Communications failure action should be considered for both an aircraft and a facility. In case of the latter, most Navy facilities have backup or emergency radio equipment plus standby or auxiliary power supplies. This system does not eliminate the possibility of a facility communications failure but reduces it to improbable. However each facility should develop an internal plan to follow in the event part or parts of the backup system do not function as designed. The AC1 or Chief may be involved in the planning or actual construction of a plan of action to reestablish communications with aircraft under control of a facility if such an emergency should arise.

Aircraft communications failures with modern, reliable equipment are uncommon, but since it is a possibility, advanced planning and training is necessary to effectively handle such a situation should it arise. When an aircraft experiences two-way communications failure, air traffic control is based on anticipated pilot actions. Pilot procedures and recommended practices are set forth in FAR's, the Airman's Information Manual, and pertinent military instructions. For information, FAR 91.127, "IFR Operations; Two-way Communications Failure" is quoted as follows:

1. Unless otherwise authorized by ATC, each pilot who has two-way radio communications failure when operating under IFR shall comply with the rules of FAR 91.127.

2. VFR conditions. If the failure occurs in VFR conditions, or if VFR conditions are encountered after the failure, each pilot shall continue the flight under VFR and land as soon as practicable.

3. IFR conditions. If the failure occurs in IFR conditions, or if the provisions of the preceding paragraph cannot be complied with, each pilot shall continue the flight according to the following:

a. Route.

(1) By the route assigned in the last ATC clearance received;

(2) If being radar vectored, by the direct route from the point of radio failure to the fix, route, or airway specified in the vector clearance;

(3) In the absence of an assigned route, by the route that ATC has advised may be expected in a further clearance; or

(4) In the absence of an assigned route or a route that ATC has advised may be expected in a further clearance, by the route filed in the flight plan.

b. Altitude. At the highest of the following altitudes or flight levels:

(1) The altitude or flight level assigned in the last ATC clearance received;

(2) The minimum altitude (converted to minimum flight level if appropriate) for IFR operations; or

(3) The altitude or flight level ATC has advised may be expected in a further clearance.

c. Climb. When it is necessary to climb in order to comply with the preceding paragraph, the following applies:

(1) Climb to the assigned altitude or flight level in accordance with the last ATC clearance received;

(2) Climb to the minimum altitude for IFR operation at the time or place necessary to comply with that minimum; or

(3) Climb to the altitude or flight level ATC has advised may be expected in a further clearance at the time or place included in the expect-further-clearance.

d. Leave holding fix. If holding instructions have been received, leave the holding fix at the expect-further-clearance time received, or, if an expected-approach-clearance time has been received, leave the holding fix in order to arrive over the fix from which the approach begins as close as possible to the expected approach clearance time.

e. Descent. Begin descent from the en route altitude or flight level upon reaching the fix from which the approach begins, but not before—

(1) The expect-approach-clearance time (if received); or

(2) If no expect-approach-clearance time has been received, the estimated time of arrival, shown on the flight plan, as amended with ATC.

CONTROL ACTION

Although SAR is not limited to aircraft incidents the restrictive nature of this training manual limits this discussion to subject matter concerning air traffic control. AC's by virtue

TS80110878

of their job of keeping track of each aircraft operation may be the first to suspect an emergency situation. In nearly every instance, a timely alert to the appropriate SAR facility or organization is an essential contribution to a successful mission.

Each ship or station has its own crash and rescue bill which the AC1 or Chief may be involved in drafting, updating, or revising. This bill is a collection from various publications of the necessary information and action required locally. This bill is included as part of the local Air Operations Manual and is the guideline to be followed by AC's in the command during an actual incident on or near the station and in training junior or new personnel.

Flight Service Stations serve as the central points for collecting and disseminating information on overdue or missing aircraft which are not on an IFR flight plan.

Centers serve as the central points for collecting information, for coordinating with SAR, and for conducting a communications search by distributing any necessary ALNOT's concerning:

1. Overdue or missing IFR aircraft.
2. IFR aircraft in an emergency situation occurring in their respective areas.
3. Overdue or missing aircraft which have been authorized to operate in accordance with special VFR.

For more information on action taken by the appropriate facility for overdue or missing aircraft, refer to AC 3 & 2, NavPers 10367-D, chapter 3.

Traffic Restrictions

Unless radar separation is used, when an IFR aircraft is unreported, the facility responsible must restrict or suspend other IFR traffic for 30 minutes after whichever of the following times is applicable:

1. The time at which approach clearance was delivered to the pilot.
2. The expected approach clearance time delivered to the pilot.
3. The arrival time over the navaid serving the destination airport.
4. The current estimate—either the control facility's or the pilot's, whichever is later—at the navaid serving the destination airport.

Lighting Requirements

The runway lights, approach lights, and all other required airport lighting systems must be operated for at least 30 minutes before the ETA of the unreported aircraft until the aircraft has been located or until 30 minutes after its fuel supply is estimated to be exhausted.

Traffic Resumption

After the 30 minute traffic suspension period has expired, normal air traffic control may be resumed if the operators or pilots of other aircraft concerned agree.

Communications Failure

The following action, as appropriate, may be taken if two-way radio communications is lost with an aircraft:

1. Broadcast clearances through any available means of communications including the voice feature of navaids.

2. Attempt to reestablish communication by requesting the pilot of the aircraft to use his transponder or make turns to acknowledge clearances and answer questions. Consider the following possibilities using the transponder:
   a. Request the pilot to reply Mode A/3 IDENT.
   b. Request the pilot to reply on an identification code (1200 or 2200).
   c. Request the pilot change to STANDBY for a sufficient length of time for the controller to be sure that the lack of target is the result of the requested action.

3. Broadcast a clearance for the aircraft to proceed to its filed alternate airport at the MEA, if the aircraft operator concurs.

VFR AIRCRAFT IN WEATHER DIFFICULTY

If the pilot of a VFR aircraft should request assistance when he is about to encounter IFR weather conditions, he should be instructed to contact the appropriate facility responsible for the area concerned. If your facility is not the control facility and the pilot advises he is unable to contact the control facility, you may be required to relay information and clearances necessary to assist the VFR aircraft.

0730110829

At radar facilities, if VFR traffic requests radar assistance when encountering or about to encounter IFR weather conditions, the controller should first determine if the pilot is capable and qualified for IFR flight. If the pilot is qualified for IFR, he should be requested to file an IFR flight plan after which a clearance may be issued after coordination with the necessary facility. If it is determined that the pilot is not qualified or capable of IFR flight, then the following actions as appropriate should be taken:

1. Inform the pilot of airports where VFR conditions are reported, provide other available pertinent weather information, and determine if the pilot will elect to conduct VFR flight to such an airport.

2. If the pilot does not elect to proceed to an airport as described in the preceding paragraph, radar assistance should be provided if the pilot declares an emergency or if the controller can determine the exact nature of the radar service the pilot desires.

3. If the aircraft has already encountered IFR conditions, the pilot should be informed of the minimum safe altitude. If the aircraft is below the minimum safe altitude and sufficiently accurate position information has been received or radar identification is established, a heading may be furnished on which to climb to reach minimum safe altitude.

Assistance Techniques

When providing radar assistance to a pilot not qualified to operate in IFR conditions, the following techniques should be used to the extent possible:

1. Avoid radio frequency changes except when necessary to provide a clear communications channel.
2. Turns should be made when the aircraft is in VFR conditions so it will be in a position to fly a straight course when in IFR conditions.
3. The pilot should be instructed to lower the landing gear and slow the aircraft to approach speed while in VFR conditions.
4. Requiring a climb or descent while in a turn and in IFR conditions should be avoided.
5. Abrupt maneuvers should be avoided.
6. Vector such aircraft to VFR weather conditions if possible.

LOCATOR BEACON SIGNALS

Some aircraft and/or occupants carry locator beacons of various types which are independently powered devices emitting a distinctive tone for homing purposes on 121.5 and/or 243.0 MHz. Several types of signals are produced by these beacons such as a beep beep, or a warbling or steady tone. The latest Navy equipment provides for two-way radio communication. Since the emergency signal from a locator beacon may only be heard for a short period of time, quick action is essential.

When a locator beacon signal is heard or reported the following steps are recommended:

1. Attempt to obtain a bearing on the signal.

2. Notify the DF net control.

3. Forward bearings and any other pertinent information to the DF net control.

DIRECTION FINDER SERVICE

Providing practice DF steers or approaches to aircraft that are operating normally and in accordance with VFR might be considered a relatively simple matter. The only real action required is to provide the necessary headings for the pilot to comply with to accomplish the desired operation. On the other hand, an emergency situation or IFR operation can complicate the procedure somewhat requiring the controller to provide information to insure proper terrain clearance, proper position relative to controlled airspace, and possibly a complete instrument approach plus coordination with other facilities and separation from other traffic.

To assist controllers, certain guidelines may be established to identify the steps necessary when providing DF service to an aircraft in emergency as follows:

1. It should be determined if the aircraft concerned is on a flight plan, whether it is in VFR or IFR weather conditions, the amount of fuel remaining, its altitude/FL, and heading.

2. If it is determined that the aircraft is not on an IFR flight plan and is in VFR weather conditions, the pilot should be advised to remain in VFR conditions.

3. If it is determined that the aircraft is operating in IFR weather conditions, the pilot should be informed of the minimum safe

0580110830

altitude and the controller must coordinate with the appropriate control facility for the purpose of separation from other IFR traffic and flight progress information if the aircraft in distress is operating in accordance with an IFR clearance.

4. The DF net control should be alerted if the pilot declares an emergency or is lost, even though the aircraft may be radar identified (unless the aircraft is sighted visually). This will provide for capability of cross checks and continued assistance under almost any conditions such as radar failure or loss of radar target due to altitude, etc.

Generally speaking, a DF net's area of coverage would be an ARTCC's area of responsibility (flight advisory area) with the ARTCC as net control. However, the ARTCC may designate any DF station as DF net control and if a center's area includes two DF nets, a control station for each would be designated. When alerted by a station of an emergency which may require DF assistance, the center or net control, as appropriate, can further alert those DF stations within the network which may be required to assist. The DF station having primary responsibility for radio communications with the distress aircraft would be considered the primary station and all other DF stations on the net remain silent on the frequency in use. Whenever possible, radar identification of the distressed aircraft should be accomplished. All courses received from the DF stations are plotted on a plotting board to establish a fix. A minimum of two DF courses are required to form or establish a fix. However, one station can determine a no-wind position of the aircraft by the time or distance method of determining position in relation to a DF station expressed in terms of miles or minutes from the station. For more detailed information on operation and procedure for direction finding, refer to NavPers 10367-D, AC 3 & 2, chapter 4.

Under emergency conditions where a standard instrument approach cannot be executed, an instrument approach based on DF guidance may be provided. DF approaches are established at some facilities for this purpose in the same manner as TACAN and radar approaches. These procedures are described in the TERP's handbook. Generally a teardrop type approach is used for low altitude operations and a triangle type approach for high altitude operations. Both types consist of an outbound leg, turn(s), and an inbound leg with an angular difference of 45° from the reciprocal of the outbound course. The triangle type procedure includes a base leg before turn to final. Both lost communications procedure and missed approach procedure instructions must be issued to the pilot of an aircraft being provided a DF approach. Generally, the approach criteria for DF approaches is the same as that for ADF approach procedures. The minimums established must provide obstruction clearance in the final approach area and the circling approach area per category of aircraft. Since DF navigation is based on communications, maximum intervals between contacts for a published DF approach have been specified, as follows: while the aircraft is en route to the station prior to initial approach, 60 seconds; from initial approach fix to within an estimated 30 seconds from final station passage or missed approach point, 15 seconds; when 30 seconds or less from final station passage or missed approach point, 5 seconds.

EMERGENCY AIRPORT RECOMMENDATION

A controller handling an aircraft in distress may decide to recommend an emergency airport to the pilot. Such a decision may be reached after several essential conditions are considered, as follows: remaining fuel in relation to the distance to the recommended airport; the existing weather conditions both en route and at the recommended airport; airport conditions, such as runway length and weight capacity; navaid status; type of aircraft and pilot qualifications versus actual operation necessary to get to and land at the recommended airport; and radar vectoring, DF guidance, or homing capability to the emergency airport recommended.

When such a recommendation is made and accepted by the pilot of the distressed aircraft, every conceivable means of guidance to the emergency airport must be considered and used if necessary, including radar, DF, following another aircraft, pilotage by landmarks, or compass heading.

SEARCH AND RESCUE

Search and Rescue (SAR) is defined as the employment of available personnel and facilities

10831

in rendering aid to persons and property in distress. The development of the SAR concept as a planned undertaking is of fairly recent origin, although the recognition of the moral obligation to assist persons in distress dates back to ancient times. The rescue of military, personnel is an integral and important part of military operations. The armed forces have traditionally accepted, to the extent practicable a moral or humanitarian obligation to aid non-military persons and property in distress. This has been further implemented by the National SAR Plan.

The National SAR Plan assigns search and rescue responsibility as follows:

1. To the military agencies—Conducting physical search and rescue operations.

2. To the FAA—

a. Providing emergency service to aircraft in distress.

b. Assuring that SAR procedures will be initiated if an aircraft becomes overdue or unreported. This is accomplished through the ATC system for IFR aircraft and the VFR flight plan service provided by Flight Service Stations for VFR aircraft.

c. Attempting to locate overdue or unreported aircraft by INREQ and ALNOT communications search.

d. Cooperating in the physical search by making all possible facilities available for use of the searching agencies.

Under the National Search and Rescue Plan the facilities of all these agencies, as well as those of the Navy, are integrated into a single SAR network to provide maximum efficiency and economy in the prosecution of any SAR mission. The U.S. Coast Guard is responsible for coordination of search and rescue for the Maritime Region, and the U.S. Air Force is responsible for coordination of search and rescue for the Inland Region. In order to carry out this responsibility, the Air Force and Coast Guard have established Rescue Coordination Centers to direct search and rescue activities within their regions. This service is available to all persons and property in distress, both civilian and military. Normally, for aircraft incidents, information will be passed to the Rescue Coordination Centers through the appropriate Air Route Traffic Control Center.

DEVELOPMENT OF SAR

The rescue of personnel in distress has become an integral and important part of naval operations. The primary objective of SAR is to save the lives of personnel in distress. It applies principally, but is not restricted to, the rescue of personnel of the Armed Forces of the United States and its allies. Successful SAR operations not only have a beneficial effect on the morale of fighting forces when a life is saved, but also aid in preserving the strength of the Armed Forces by retrieving its highly trained personnel.

The present-day concept of SAR is an outgrowth of the Air Sea Rescue Plan inaugurated by the U.S. Coast Guard in 1939. The plan became subject to expansion and additional development as a result of the U.S. Navy's role in World War II. The Navy, then engaged in operations extending over vast areas of the earth's water surface, found it necessary to develop standardized procedures for the search and rescue of its own downed air personnel and survivors of ships damaged or sunk by enemy action.

To accomplish the SAR mission, suitable surface ships and aircraft were periodically placed under the tactical command of a rescue task group commander in the area of operations. Submarines were also detailed to these missions as requested by the tactical commander. As the war progressed and the magnitude of naval operations increased, these SAR missions assumed greater importance. It became apparent that the employment of specially trained and equipped units specifically assigned to SAR duties could relieve other units of these operations which interfered with their primary missions. This procedure, when instituted, resulted in greater effectiveness on the part of all units in the performance of their respective duties.

When reports of survivors' experiences were studied, it also became apparent that additional survival equipment was needed, particularly equipment which permitted survivors themselves to assist the searchers. As a result, such items as the self-inflating liferaft, the emergency signal mirror, emergency radio transmitters, and various pyrotechnic distress signals were developed.

10832

INTERAGENCY COORDINATION

In time of peace, it is incumbent upon the U.S. Navy to take full advantage of the SAR techniques developed and facilities operated by the U.S. Coast Guard. The reason for this is that the U.S. Coast Guard is charged with the development, establishment, maintenance, and operation of aids to maritime navigation and rescue facilities which promote safety on and over the high seas, and waters subject to the jurisdiction of the United States. The Coast Guard, under its responsibilities, may render aid to persons and protect and save property at any time at any place where its facilities and personnel are available.

As a result, operational commands of the U.S. Navy may delegate to the Coast Guard such SAR functions as duties of the SAR Commander and other functions that may be jointly agreed upon by the respective commands. However, before these functions are given to the Coast Guard, full consideration must be given to the adequacy of Coast Guard facilities and other responsibilities imposed upon that service by laws. In addition to using Coast Guard SAR facilities, naval commands cooperate fully, when requested, in assisting the Coast Guard in the execution of its functions. Navy commands also keep Coast Guard commands in the area of their operations informed in detail on their SAR requirements and provide logistic assistance as requested by Coast Guard SAR operations. The extent of this assistance is governed by existing instructions and the availability of facilities and equipment.

In wartime, the Coast Guard operates as a specialized service within the naval establishment, and its responsibilities for SAR are subject to orders of the Secretary of the Navy.

The U.S. Army and the U.S. Air Force maintain SAR facilities for use in support of their own operations. The Federal Aviation Administration (FAA) of the Federal Government has broad statutory responsibility in the field of air safety. In addition, the FAA has air traffic control and communications facilities available for SAR purposes. AC 3 & 2, NavPers 10367-D, chapter 3, outlines facilities and procedures used by FAA in connection with SAR. Other federal agencies, such as the Federal Communications Commission (FCC), cooperate in SAR operations.

COMMAND AND ORGANIZATION

COMMAND PROVIDES THE AUTHORITY for the control of forces and facilities attached to SAR, while ORGANIZATION PROVIDES THE MEANS—the personnel, techniques, and procedures—necessary to carry out the mission. Command authority for a designated area or region is usually vested in one person, the SAR Coordinator. It is his responsibility to provide the organization and insure that it functions efficiently. This is achieved through the formation of the Rescue Coordination Center (RCC) and the training of assigned personnel in all operational aspects of SAR.

Authority and Responsibility of the SAR Coordinator

Responsibility for SAR is divided into several classifications, each containing certain definite assignments for SAR. Thus, commands to whom the primary responsibility has been assigned have greater duties to perform than do commands which have been assigned secondary support or informational responsibility. In spite of the division of SAR responsibility among commands, all hands possess a basic responsibility to take part in SAR operations, at any time, with or without prior direction.

Any commander responsible for SAR may designate a SAR Coordinator for his area of responsibility. In making that designation the command should be guided by the availability of facilities, the nature of SAR operations normal to the area or sphere of action, and any special qualifications of the officers under consideration.

The person directing a specific SAR mission is known as the SAR Mission Coordinator.

In general, the duties of the SAR Coordinator involve establishing operationally efficient RCC's, staffed with competently trained men and actively linked with other centers in neighboring areas or services. He must be prepared to provide all-out assistance in SAR missions, to assume tactical responsibility, to control surface and air unity in any SAR operation under his direction, and to direct or coordinate rescue operations.

The SAR Coordinator has operational control of all primary facilities assigned to him

10833

for SAR purposes. Submarines, whether primary or secondary SAR facilities, remain under the operational control of submarine force commanders. Commands exercising operational control, or higher authority, may assign secondary facilities to the SAR Coordinator for operational control for a specific incident. He coordinates the activity of all units participating in SAR incidents within the area of his responsibility, effecting coordination of all other units with those under his operational control. Coordination is to be exercised through the normal chain of command. Rescue commanders of forces afloat coordinate SAR activities incidental to the operation of these forces, regardless of the area of operation, unless other plans are mutually agreed upon by the commander of the forces afloat and the command with primary SAR responsibility in the area of operations.

At times it may be necessary for the SAR Mission Coordinator to designate an on-scene commander. An on-scene commander controls SAR operations at the scene of a distress incident when control of the mission cannot be exercised effectively by the SAR Mission Coordinator. This loss of effective control may be due to the distance between the Rescue Coordination Center (RCC) and the scene of the incident, or due to communications difficulties. The commander of the first unit at the scene to be in communication with the craft in distress, with other SAR forces, or with the RCC, assumes on-scene command until an on-scene commander has been designated by the appropriate SAR Mission Coordinator.

To provide continuity of command, any officer who is senior to the on-scene commander and who arrives subsequently is not to take over command of operations unless ordered to do so by the SAR Mission Coordinator, or unless the senior officer present decides that a change of command is essential, and so informs the SAR Mission Coordinator.

If the on-scene commander is airborne, he retains control of the mission until relieved, either by the Mission Coordinator or by mutual agreement with an adequately equipped surface craft. The SAR Mission Coordinator must be informed accordingly.

Formal designation of an on-scene commander or any change in that designation is promulgated by the SAR Mission Coordinator to all concerned.

Rescue Coordination Center (RCC)

The RCC is the heart of SAR operations. It is the place from which SAR operations are controlled and where reports of operations are received and evaluated. The primary aim of all efforts in the RCC is to conclude all rescue missions successfully and promptly. The RCC's are established by the SAR Coordinator.

RCC's may be based ashore or afloat. Where practicable, they should be located in or near an operation or information center. The RCC afloat is normally located in Air Operations. Ashore, it may be located in or adjacent to a command or information post. Wherever it is located, the RCC should have ready access to a control room, surface and air plots, communications facilities, navigational aids, direction-finding facilities, and meteorological services.

It is the responsibility of the RCC to perform the following:

1. Receive and evaluate all reports of distress.
2. Direct or coordinate the search for and rescue of survivors, keeping all interested commands and operating agencies (including the survivor's parent ship or base) fully informed, as appropriate.
3. Plot positions of all distress incidents and the tracks of all assisting aircraft.
4. Keep informed of weather, sea conditions, and other factors affecting rescue.
5. Undertake arrangements necessary for the return of rescued personnel to their ship or base.
6. Maintain a status board showing all primary rescue facilities.
7. Maintain information on secondary facilities available.
8. Guard assigned radio communications circuits.

An RCC is a primary SAR facility suitably staffed by supervisory personnel and equipped for coordinating and controlling SAR operations. RCC's vary with the physical location and the regional level on which they are operated, but all should have the common element of centralized communication and

10834

coordination. RCC's should be staffed with RCC controllers capable of acting as SAR Mission Coordinators.

SAR facilities available to RCC's are classified as primary and secondary.

PRIMARY facilities may include the following:

1. Specially equipped air and surface craft maintained in constant readiness for full-time SAR duties.
2. Other craft, including submarines, specifically assigned to SAR.
3. Ground units specially equipped and maintained in constant readiness.
4. Meteorological forecasting and advisory services.

SECONDARY facilities may include the following:

1. Local military land-based aircraft and surface craft.
2. Other aircraft suitable for SAR missions.
3. Any military facility.
4. Merchant ships, private vessels, and civilian aircraft.
5. Other means available to local authorities.

Full information concerning any significant change in the status or location of primary facilities established for and used by SAR agencies should be given widest possible dissemination by the SAR Coordinator, the SAR Mission Coordinator, or the agency concerned.

AUTOMATED MERCHANT VESSEL REPORT SYSTEM

The Automated Merchant Vessel Report System (AMVER) is an international maritime mutual assistance program. It provides important aid to the development and coordination of search and rescue efforts in the offshore ocean areas of the world during marine and aviation emergencies. Merchant ships of all nations are encouraged to voluntarily send sailing and position reports during offshore passages to the AMVER Center in New York through cooperating radio stations made available by participating countries. Information from these and meteorological reports is entered into the AMVER electronic computer which generates and maintains dead reckoning positions for the participating ships. Characteristics of ships which are valuable for determining search and rescue capability are also stored in the computer. Information concerning predicted locations and characteristics of ships plotted near the scene of an actual or potential emergency is made available to recognized SAR agencies of any nation or person in actual or potential distress for use during an emergency. Predicted positions and identification of ships are disclosed only for reasons related to maritime safety.

Surface Pictures

The basic service provided for use during emergencies is the Surface Picture (SURPIC). A SURPIC is a list of ships with SAR characteristics predicted by the computer to be within a specified geographical region at a specified time, present or future. SURPIC's are useful to aircraft commanders during an alert or emergency situation by assisting in making contingency plans in case the situation should deteriorate rapidly into a distress and a ditching become imminent.

Network of Precautionary Trackline SURPIC's in the Pacific Region

Because of the special nature of the long overwater flights in the Pacific and Indian Oceans and the associated lack or remoteness of regular SAR facilities, special services have been provided to aviation for many years by several countries. Positions of ships participating in weather reporting schemes were used to predict future locations and this information was provided to flight briefing officers by the cognizant civil aviation authority. In the United States Pacific Maritime region this service was called SAR Plan ALFA. The AMVER system has replaced Plan ALFA and has begun providing additional precautionary trackline SURPIC's to rescue centers and international flight service stations throughout the north and south central Pacific for major international flight routes. Additional routes will be added as the AMVER plot is developed in the more remote areas.

The precautionary trackline SURPIC's are predicted for a future mean time and distributed to briefing points by governmental communications networks. Copies of the SURPIC's

10836 10835

observe the output of the summing amplifier. The amplitude adjustment (screwdriver adjustment) is set on each channel so that the output from each amplifier is equal in amplitude. With the oscilloscope connected to the same point, the frequency adjustment, (a technician's adjustment) is set so that the output of each amplifier coincides with the output of the amplifiers on either side of it with no interruption of the pulse. When any of the amplifiers are changed, both of these adjustments must be performed.

This LIFMOP waveform may be transmitted at these frequencies, or it may be passed through frequency converters to increase the frequency to whatever is desired to be transmitted. It will normally be amplified by several RF amplifiers prior to being transmitted. These RF amplifiers, of necessity, have a very broad bandwidth and linear frequency response to avoid any type of distortion of the LIFMOP waveform. The waveform shown in figure 15-19 leaves the summing amplifier with some amplitude variations. It is desirable that the transmitted waveform have no variations of amplitude. Normally, the waveform will be passed through a limiter prior to transmit to remove these amplitude variations.

The transmitted pulse will be rectangular, swept in frequency over 10 mc, and 10 μsec in duration. It is composed of the combined outputs of all 10 filters.

PULSE COMPRESSION

This operation is basically the inverse of pulse expansion. That is when a 10-μsec target return is received, it is compressed so that the receiver output is a 0.1-μsec echo.

Echo Return from a Target

For discussion purposes assume that a target is located a distance from the receiving antenna so that a 100-μsec of travel time will be required for the return echo to reach the receiver antenna. The lowest frequency was the first to leave the transmitter, and the first to strike the target; thus, the lowest frequency will be the first to be picked up by the receiving antenna. (It will be returned 100-μsec after it strikes the target.) The highest frequency transmitted did not leave the transmitter until 10 μsec later. It did not strike the target until 10 μsec after the lowest frequency struck the target. Therefore, it was not returned to the receiving antenna until 10 μsec after the lowest frequency was received. Refer to figure 15-20.

Figure 15-20. —Time function of transmitted pulse.

1081

are normally made available by the briefing station for inclusion in the preflight briefing kit. The aircraft commander can easily calculate the approximate position of ships of interest for the time estimated abeam and place the information on the navigation chart.

10836

CHAPTER 7

CVA/CVS PROCEDURES

As defined by naval regulations, the Operations Officer of an aircraft carrier is responsible for the control of airborne aircraft operating from the carrier except those assigned to other authority. The primary facility through which the Operations Officer exercises his authority and responsibility for safe and effecive control of airborne aircraft is the Carrier Air Traffic Control Center (CATCC). The Air Operations Officer is responsible to the Operations Officer for all matters pertaining to flight operations and for the proper functioning of the CATCC. The CATCC is responsible for the status keeping of all carrier air operations and control of all airborne aircraft under the Operations Officer's cognizance except for the following:

1. The Air Officer is responsible for visual control of aircraft operating in the carrier control zone. He is the clearing authority for the carrier control zone.
2. The Landing Signal Officer is responsible for visual control of arriving aircraft immediately prior to landing.
3. The CIC Officer is responsible for mission control of aircraft assigned to him.

CVA/CVS INSTRUMENT PROCEDURES

CVA/CVS instrument procedures are necessarily different from those applicable ashore. The basic necessity for safe and efficient procedures may be even more prevalent aboard carriers. The conditions which affect CVA/CVS instrument procedures are of a different nature since the carrier is a mobile airfield normally operating in areas where obstruction clearance presents little if any problem. This discussion is limited in content concerning the overall picture of CATCC. The CVA/CVS NATOPS Manual should be referred to for a more detailed study of the subject matter.

MARSHAL PROCEDURE

A common question asked by trainees is "Why the word MARSHAL?" This is good question. Apparently reference is being made to one of the many meanings of the word, which is "to arrange objects or people in order." Compared to approach procedure ashore, a marshal fix would be the same as the initial approach fix.

A primary TACAN marshal fix is normally established on a predetermined radial at a distance appropriate for the type aircraft. The radial is established with reference to the base recovery course (BRC). The BRC is the ship's magnetic heading for recovery of aircraft.

For jet aircraft, the primary TACAN marshal fix is normally on the 170 radial, relative to the BRC, at a distance of 15 miles plus 1 mile for each 1,000 feet of altitude.

For propeller aircraft aboard CVA's, the primary TACAN marshal fix is on the 125 radial relative to the BRC at a distance of 7 miles plus 1 mile for every 1,000 feet of altitude as assigned.

Turboprop aircraft aboard CVA's may use either the jet or the prop marshal as required.

Aboard CVS's, the primary TACAN marshal fix is on the 170 radial relative to the BRC at a distance of 10 miles plus 1 mile for every 1,000 feet of altitude as assigned. This marshal could not be used if jet aircraft were being recovered.

The primary TACAN marshal fix for helicopters is on the 090 radial relative to the BRC at a distance of 5 miles, plus 1 mile for every

10837

500 feet of altitude as assigned, starting at 500 feet.

A secondary TACAN marshal fix for propeller air craft may be designated on CVS's; for example, the 225 radial relative to the BRC at a distance of 7 miles, plus 1 mile for each 1,000 feet of altitude as assigned.

Alternate marshal fixes may be established on radials at 30-degree intervals, clockwise from the primary marshal radial, or CVS's may establish an overhead marshal. In the event of TACAN failure or restricted airspace, CATCC may specify overhead holding in lieu of an alternate marshal.

In the event an aircraft or flight cannot reach the assigned marshal point in time to make an assigned approach time due to mission, fuel state, or ordnance load, an en route radar approach may be used to place the flight in the proper approach sequence. Positive radar control is required for all en route descents.

Marshal Pattern and Altitude

Unless otherwise specified in the operations order or instructions issued by marshal control, the marshal pattern should be a 6-minute racetrack pattern. The inbound leg should pass over the marshal fix. Direction of turn for each pattern is depicted on the respective approach chart.

Every effort should be made to anticipate weather conditions and provide marshaling in visual conditions if practical. Aircraft below an overcast cloud layer should not be required to climb into the overcast to comply with marshal altitude limits if approach control can maintain the interval and sequence from the lower altitude. Aircraft above an overcast cloud layer should be assigned altitudes above the overcast and retained in formation where possible.

Formation flights should be limited to a maximum of four aircraft at any one assigned altitude. Under IFR weather conditions, a section of two aircraft is the maximum number authorized in any one flight and hence at the same marshal altitude.

Fixed-wing aircraft are normally assigned marshal altitudes which provide 1,000 feet vertical separation except where required to provide 2,000 feet above 29,000 feet. A CVS using a secondary marshal fix should assign thousand foot altitudes (1,000, 2,000, etc.) at the primary marshal fix and thousand-plus-500 (1,500, 2,500, etc.) at the secondary marshal fix.

Helicopters are assigned altitudes at marshal which provide 500 feet vertical separation.

APPROACH PROCEDURE

Approach procedures described and depicted herein are primarily for single carrier operations. However, with slight modifications they can be used for multicarrier operations; letdown under reduced navigation and control, using a plane guard destroyer's navaids; and during EMCON conditions.

Figures 7-1 through 7-8 are examples of approaches designed for use on carriers regardless of weather conditions. Each ship should utilize the standard approaches so that pilots who transition to other ships will encounter minimum changes in operating procedures.

Each pilot adjusts his holding pattern to depart the marshal fix at the assigned expected approach time. Early or late departures from the marshal fix must be reported to approach control so that adjustment in the interval can be made for safe separation.

Changes in radio communications frequencies and IFF codes should not be required of the pilot after platform (5,000 feet) except under emergency conditions.

Letdown/Penetration

Jet aircraft descend at 250 knots and 4,000 feet per minute until platform is reached. At platform the descent is shallowed to 2,000 feet per minute. They should arrive at the 10-mile gate at 1,200 feet and 250 knots. The pilot will commence transition of his aircraft to landing configuration at the 10-mile gate unless directed otherwise by CCA.

Turboprop aircraft, when in a jet marshal, will fly the letdown/penetration in the same manner as that prescribed for jet aircraft.

Propeller aircraft descend at 140 knots and 1,000 feet per minute from the marshal fix to arrive at the 6-mile gate at 1,200 feet.

10845

It can be seen that a definite time versus frequency relationship exists during the 10 μsec that the returning echo is felt on the receiver input. At any time, the frequency can be determined and, therefore, which channel is receiving a signal. For instance, at T_0 plus 106 μsec, the frequency which will enter channel No. 6 is just arriving at the receiver antenna. This means that the frequencies affecting channels 1 thru 5 have already arrived, and channels 7 thru 10 are yet to come.

If the returned echo is applied to the matched filter as it is now (lowest frequency first), by action of the L and C of the tanks, the filter would tend to expand the signal again, rather than compress it as is desired. FOR THE PULSES TO BE COMPRESSED, THE FREQUENCY RELATIONSHIPS MUST BE REVERSED. That is, the returned echo must be turned around so that the highest frequency enters the matched filter first, and the lowest frequency enters last, or 10 μsec later. This is easily accomplished by sideband inversion.

SIDEBAND INVERSION. —Sideband inversion is a process of inverting the frequencies contained in the upper and lower sidebands during the process of frequency conversion. This process occurs any time the local oscillator is tuned ABOVE the frequency to be converted, and the DIFFERENCE frequency is selected. (See fig. 15-21.)

NOTE: The reader should be aware that the frequency values used in figure 15-21 are arbitrary values and were selected only to illustrate sideband inversion.

From figure 15-21, it can be seen that when the upper sideband (101 mc) passes through the mixer, the difference frequency produced is 9 mc. When the lower sideband frequency (99 mc) is converted, the difference will be 11 mc. Thus, the highest incoming RF produces the lowest difference frequency, and the lowest RF produced the highest difference frequency. In the case of the pulse compression radar under discussion, the returned echo is passed through a frequency conversion stage for the purpose of sideband inverting the frequencies. The lowest frequency which was first returned will become the highest frequency after sideband inversion (95 mc will emerge as 105 mc). The highest frequency (105 mc), returning last will emerge from the mixer as 95 mc. Because of this process, the entire frequency content of the returning pulse will be reversed. After this inversion, the echo is now ready to be applied to the matched filters for pulse compression.

Figure 15-21. —Sideband inversion block diagram

Action of Matched Filter on the Returned Echo

The returning pulse, AFTER SIDEBAND INVERSION, is once again applied to the parallel inputs of all 10 matched filter channels. The difference between the input to the matched filter, now on the pulse compression function, and the input for the pulse expansion function on transmit is that on pulse expansion, ALL frequencies (each one in phase) were present at EACH channel at the SAME TIME. But on pulse compression (or receive), the frequencies arrive ONE AT A TIME, each one separated from the others by a small phase and time difference. The first frequency to arrive, at T_0 plus 100 μsec, is the highest input frequency to the filter after conversion, and 10 μsec later, at T_0 plus 110 μsec, the lowest input frequency after conversion arrives at the filter. It must be noted that as each individual frequency arrives, it is present at the input to each one of the 10 channels simultaneously.

The highest frequency (after conversion), being the first to arrive, is applied directly to the matched input filter. Since this frequency is within the bandpass of ONLY channel 10, it will affect only channel 10. Before it can be applied to the tuned amplifier of channel 10, it receives a 9-μsec delay. Therefore, this frequency finally is present at the tuned amplifier of channel 10 at T_0 plus 109-μsec. For the next 1-μsec of time, all of the frequencies within the bandpass of channel 10 will arrive and be processed. The highest frequency (105 mc) at T_0 plus 109 μsec, is

10846

Helicopters descend at 90 knots and 500 feet per minute from the marshal fix to arrive at the 3-mile gate at 500 feet.

Correction to Final Bearing

If conditions were always stable during carrier operations, then there would be no reason to alter the ship's heading once a base recovery course had been decided upon. In the case of the CVA jet letdown/penetration, the final bearing would be the same as the reciprocal of the marshal radial if no changes occur. But often the variable elements exercise their option to change, such as a wind shift, frontal passage resulting in variable wind, proximity to land masses, etc., which require a change to the BRC upon which CATCC has based the recovery approach procedure. If aircraft are already in the letdown/penetration or are in the holding pattern at marshal fix when the change occurs, then a change to the final bearing is required. When this happens the pilots concerned must be informed of the situation and corrections must be made to intercept the new final bearing.

Jet or turboprop aircraft on TACAN/RADAR approaches initiate correction from the marshal radial to the final bearing at 20 miles. If the final bearing is within 10 degrees of the reciprocal of the marshal radial, a gradual correction is made. If the difference is more than 10 degrees, the pilot will make a 30-degree turn to intercept the final bearing. If the aircraft is not established on the final bearing at 12 miles, then the pilot will fly the 12-mile arc until intercepting the final bearing.

Prop and turboprop aircraft on a TACAN/RADAR approach would correct from the marshal radial to the final bearing with a 45-degree correction turn from the inbound heading in the holding pattern when departing marshal. This heading would be held until the final bearing is reached or, if the 6-mile arc is reached first, then the 6-mile arc would be flown until intercepting the final bearing.

Nonprecision Final Approach

When precision approach radar or suitable visual landing aids are not available, aircraft on final approach will continue descent to 600 feet after passing the 6-mile gate. The final controller will provide sufficient information to the pilot for him to maintain an accurate azimuth and altitude until reaching nonprecision minimums.

Precision Final Approach

Jet and turboprop aircraft pass through the 6-mile gate at 1,200 feet and 150 knots in a landing configuration. The altitude of 1,200 feet is maintained at approach speed until intercepting the glidepath (approximately 3 miles) unless otherwise directed by the final controller.

Propeller aircraft pass through the 3-mile gate at 1,200 feet in a landing configuration and maintain 1,200 feet until intercepting the glidepath or until otherwise directed by the final controller.

Helicopters pass through the 3-mile gate at 500 feet in a landing configuration and maintain 500 feet until interception of the glidepath or until otherwise directed by the final controller.

When precision radar is available, precision final approach procedures should be used for all Case III (IFR letdown and approach) recoveries. CCA will furnish glidepath and azimuth control until the aircraft on approach reaches shipboard PAR minimums or until the LSO takes control.

AWCLS Final Approach

The letdown/penetration portion of an All Weather Carrier Landing System (AWCLS) approach is the same as previously described to a point 4 to 6 miles from the ship on final at an altitude of 1,200 feet.

If a mode IA approach (automatic to minimums and manual takeover to touchdown) is to be conducted, the following will transpire:

1. At 4 to 6 miles on final, the pilot should receive a landing check discrete signal to indicate positive data link communications between the aircraft and the ship.
2. The SPN 10/42 controller should acquire the aircraft between 3.5 and 4 miles and initiate lockon.
3. When the pilot has the aircraft in the proper attitude and engages the autopilot, he will report COUPLED to the controller.

10847

4. The pilot should report receiving comand control signals via data link by reporting COMMAND CONTROL to the controller.

5. The pilot should be given a voice warning, as the aircraft approaches within 1 mile, that he is approaching minimums.

6. At one-half mile, the pilot will be informed by the controller, ONE-HALF MILE, AT MINIMUMS, UNCOUPLING NOW. The pilot resumes control of the aircraft and continues the approach.

7. If the pilot reports MEATBALL earlier than one-half mile, the controller should downgrade the approach to mode II (manual approach using the ILS type instrument (needles) in the aircraft) and transmit UNCOUPLING NOW.

If a mode II approach is to be conducted, the following should transpire:

1. At 4 to 6 miles on final, the pilot should receive the landing check discrete signal to indicate positive data link communications between the aircraft and the ship.

2. The SPN 10/42 controller should acquire the aircraft between 3.5 and 4 miles and initiate lockon.

3. After lockon, if the instruments in the cockpit are functioning properly, the pilot will report NEEDLES and fly the approach manually by reference to the instruments.

4. The pilot should receive a warning from the controller that his aircraft is at 1 mile and approaching mode II minimums.

5. At one-half mile the pilot should be informed by the controller that his aircraft is at one-half mile and passing through mode II minimums. The pilot should acquire the MEATBALL and complete the approach.

Approach Minimums

The commanding officer establishes approach minimums for his ship which reflect significant changes in operational capabilities, such as may be occasioned by decreased/increased proficieny of the CATCC or embarked air wing/group. However, absolute minimums are established as follows:

1. PAR, Mode IA and II—200 and 1/2.
2. Nonprecision approaches:
   a. Jet—600 and 1 1/4.
   b. Prop/turboprop—400 and 1.
   c. Helo—300 and 3/4.

When a suitable BINGO field is available, aircraft may not commence an approach when the reported weather is below the minimums as previously described unless it has been determined that the aircraft has enough fuel to proceed to the BINGO field in the event of a missed approach.

MISSED APPROACH/WAVEOFF/BOLTER

In the event of a missed approach, waveoff, or bolter, fixed-wing aircraft climb straight ahead on the extended reciprocal of the final bearing to a minimum of 600 feet and wait for instructions from the waveoff/bolter controller. Helicopters climb straight ahead on the extended reciprocal of the final bearing to 300 feet and await instructions.

If instructions are not received prior to reaching 4 miles or 2 minutes ahead of the ship, the pilot will attempt to make contact with the ship, giving indentification and position. If instructions are still not received, the pilot will assume communications failure and execute a turn downwind, reporting DOWNWIND ABEAM. If he still has no radio contact, the pilot will proceed downwind; and if in a fixed-wing aircraft, he will commence a turn to final at 4 miles DME. If in a helicopter, the pilot will reenter through the 3-mile gate.

In the event the deck becomes fouled or an excessive number of aircraft bolter or are waved off, the CCA officer will issue DELTA via the controllers to all aircraft. The following actions should be initiated:

1. Aircraft in holding. They should continue to hold and await assignment of a new expected approach time. Pilots should acknowledge receipt of DELTA. If the pilot of an aircraft experiences radio failure after receiving the DELTA, he should commence approach at 6 minutes after the assigned expected approach time.

2. Aircraft on approach above platform. They should level off at the next lower odd altitude and hold on the inbound bearing at a range in miles equal to 1 mile for each thousand feet of actual altitude plus 15 miles for jets, 7 miles for props, and 5 miles for helocopters. The holding pattern should be the same as the original marshal holding pattern. Pilots should

10848

acknowledge receipt of DELTA, repeating distance and altitude. Pilots experiencing radio failure after receiving DELTA would depart the holding fix 6 minutes after the time of receipt of DELTA.

3. Aircraft on approach below platform. They should continue a normal approach and await specific instructions prior to dumping fuel.

4. A new expected approach time should be assigned as soon as possible by approach control with a minimum of 6 minutes delay before continuing descent. If a pilot should experience radio failure prior to receiving a new expected approach time, he would depart the holding fix 6 minutes after receiving DELTA and continue penetration to the last known final bearing.

DEPARTURE PROCEDURE

Departure procedures are based upon the assignment of TACAN radials for the purpose of providing lateral separation. The minimum standard separation of departure radials under IFR weather conditions is 20 degrees.

The assignment of departure radials is normally dependent on the following:

1. Mission of the aircraft.
2. Number of carriers in the formation.
3. Topographical features in the area.
4. Those radials reserved for emergencies, letdowns, or propeller aircraft and helicopter holding.

Direct routing should be utilized as much as possible in order to lessen delay time in the execution of departures.

CARRIER AIR TRAFFIC CONTROL

Existing weather in the ship's control area and control zone is the most prominent factor affecting the degree of control necessary. The type of control to be employed during departure and recovery operations is determined by the Air Operations Officer unless specified by higher authority. In periods of reduced ceiling and/or visibility, electronic air traffic control techniques must be utilized to provide separation and maximum safety.

CONTROL CRITERIA

The degree of control exercised by CATCC is described as close control, advisory control, or monitor control.

Close control is defined as a form of air traffic control in which the controlling agency has radar and radio contact with the aircraft being controlled. Published approach or departure procedures are complied with or specific assignments regarding heading and altitude are issued by the controller. Vertical separation is provided by requiring pilots to maintain assigned altitudes or flight levels while lateral or longitudinal separation is provided by the controller. Speed changes may be directed by the controller.

Close control is utilized when the following conditions exist:

1. Ceilings of 1,000 feet or less for fixed-wing operations or 500 feet or less for helicopters.
2. Flight visibility of 3 miles or less for fixed-wing operations or 1 mile or less for helicopters.
3. Whenever flight operations are conducted between one-half hour after sunset and one-half hour before sunrise, except as modified by the Officer in Tactical Command (OTC) or the commanding officer.
4. During mandatory letdown in thunderstorm areas.
5. In any other situation where supervisory personnel can anticipate weather phenomena that might cause difficulty to pilots.

Advisory control is a form of air traffic control in that the controlling agency maintains radio and radar contact with aircraft under its cognizance and provides traffic advisories. Traffic separation is the responsibility of the pilot making use of the assistance provided by the agency. Advisory control must be utilized when the traffic density in an operating area requires a higher degree of control for safety of flight than required under the see-and-be-seen method. Advisory control is normally limited to VFR weather conditions and is recommended for all operations in or adjacent to oceanic control areas or routes.

Monitor control is the monitoring of radar and radio channels for emergency transmissions. Monitor control must be utilized only

10849

when aircraft are operating in VFR weather conditions outside of controlled airspace and the responsibility for separation from other traffic can be safely assumed by the pilot.

SEPARATION CRITERIA

The following criteria are provided as guidance for Carrier Air Traffic Controllers in the control of aircraft under instrument conditions. Either lateral or vertical separation will be provided. These restrictions do not apply to launch and recovery operations or tactical maneuvers.

1. Lateral separation:

a. Aircraft operating within 50 miles of the monitoring antenna—at least 3 miles.

b. Aircraft operating at more than 50 miles from the monitoring antenna—at least 5 miles.

2. Vertical separation:

a. Aircraft operating at altitudes up to and including 29,000 feet must be separated by 1,000 feet except that 500 feet may be permitted for propeller driven aircraft when required.

b. Aircraft operating at altitudes above 29,000 feet must be separated by 2,000 feet.

c. Helicopters must be separated by 500 feet.

APPROACH CRITERIA

The Air Operations Officer determines the type of approach and the required degree of control considering weather in the approach area as follows:

1. Case I, visual descent/approach. This approach may be utilized when it can be anticipated that flights will not encounter instrument weather conditions at any time during the descent, break, and final approach. A ceiling of 3,000 feet and 5 miles visibility within the carrier control zone is required for CVA's to utilize Case I procedures. The pilot retains full responsibility for proper navigation and separation from other aircraft. The pilot should be advised of the expected Charlie time and changed to tower control after reporting sighting the ship.

2. Case II, controlled descent/visual approach. This procedure should be utilized during daylight hours when weather conditions are such that flights may encounter instrument conditions during the descent, but visual conditions exist at the ship down to the following ceiling and visibility minimums:

a. 1,000 feet and 3 miles.
b. 900 feet and 4 miles.
c. 800 feet and 5 miles.
d. 700 feet and 6 miles.

Close control must be utilized until the pilot reports the ship in sight. The maximum number of jet aircraft in the pattern is limited to 6 when the ceiling and visibility are less than 1,500 feet and 5 miles.

3. Case III, controlled descent/approach. This procedure should be utilized whenever existing weather at the ship is below Case II minimums and during all flight operations between one-half hour after sunset and one-half hour before sunrise, except as modified by the OTC or commanding officer.

ARRIVAL PROCEDURES

On entering the carrier control area, inbound flights will normally be turned over to CATCC for further clearance. The flight leader should provide CATCC with the necessary information such as position, altitude, low fuel state in the flight, number of aircraft, type of AWCLS approach requested, and other pertinent information including navaid status, hung ordnance, weather, etc., which may affect the recovery. CATCC should provide the flight leader with marshal instructions, steer to marshal (if required), type of recovery, approach time or ramp time, altimeter setting and weather, time check, and expected final bearing.

Case I Procedure

Essential information is issued to the flight leader and updated if necessary. When the flight leader reports the ship in sight, the center should switch the flight to tower control.

Case II Procedure

The CATCC will control the descent until VFR weather conditions are reached. Division

10850

penetrations should not be made through an overcast that is more than 10,000 feet thick with a ceiling of less than 3,000 feet. Flight leaders should squawk normal and follow reporting procedures for Case III until the flight has broken into the clear beneath the clouds and has the ship in sight. The flight leader will then be switched to tower control and proceed as in Case I.

Case III Procedure

CATCC controls the descent and approach. This type of recovery should only be made by single aircraft except in those cases where an aircraft with inoperative radio or nagivational equipment is brought down on the wing of another aircraft. Formation penetrations/approaches by dissimilar aircraft should not be attempted except in extreme circumstances where no safer options are available to effect recovery. Directing a recovery in adverse weather conditions where alternate airports are not available demands the utmost proficiency, mutual confidence, and cooperation between pilot and controller. Marshal controllers must insure that pilots under their control have all the appropriate information necessary for a successful approach prior to commencing approach. This includes the following:

1. Expected approach time.
2. Altimeter setting.
3. Final control frequency.
4. Type of approach.
5. Final bearing.
6. Time check.
7. Ceiling, visibility, and deck conditions.
8. Divert field/data.

The marshal controller will hand off the aircraft to the approach controller as they depart the marshal fix. Unless weather or operating circumstances dictate otherwise, aircraft departing the same marshal fix are normally separated by 1 minute. Expected approach time adjustments may be made for greater separation as necessitated by varying models and numbers of aircraft, type of approach, bolter, and waveoff traffic.

Positive radar identification should be accomplished by the receiving controller prior to transfer of control. Control may be transferred only after the receiving controller has notified the transferring controller that positive radar contact exists. Approach controllers maintain control until handoff to the final controller is accomplished. Changes in radiofrequencies and IFF code must be made no lower than platform altitude except under emergency conditions.

When precision approach radar is available, precision final approach procedures are used by CATCC for Case III arrivals. In such cases, CCA furnishes glideslope and azimuth information and controls the aircraft until it reaches PAR minimums or the LSO takes over. When precision approach radar or suitable visual landing aids are not available, aircraft on final approach will continue descent to 600 feet after passing the 6-mile gate. The final controller will provide sufficient information to the pilot for him to maintain an accurate azimuth and altitude until reaching nonprecision minimums.

DEPARTURE PROCEDURE

Primary responsibility for adherence to the assigned departure rests with the pilot; however, advisory control is normally exercised with a shift to close control if weather conditions require, upon request, or when the assigned departure is not being adhered to. After launch, CATCC takes the following action:

1. Record flight data as required on status boards.
2. Insure that communications and positive track are established to the extent possible under existing EMCON conditions.
3. Request navaid checks as necessary.
4. Maintain advisory control of departing point to point flights until pilots shift to en route frequencies and of other aircraft until control is accepted by CIC or another controlling agency.
5. Before releasing aircraft to another controlling agency, CATCC should give each pilot or flight leader any pertinent information such as changes in PIM or mission.
6. When transferring control to CIC, include the range and bearing of the aircraft being transferred and insure that CIC acknowledges assumption of control.
7. File flight plans as necessary.

Aircraft are normally launched on the departure frequency which is monitored by the

10851

tower. Condition aircraft (conditions I through IV) represent various states of aircraft readiness concerning repsonse time when ordered to launch. Condition I is the minimum possible and IV is the maximum allowable. They are determined by appropriate authority, depending upon the tactical situation as it exists initially and as it changes. CAP (combat air patrol, the ships defense) aircraft will be launched on a frequency designated by CIC and monitored by the tower.

Single-frequency departures are highly desirable and should be utilized whenever possible. Where single-frequency departures are not possible, single-piloted aircraft should not be required to change radiofrequency or IFF codes after launch until the aircraft are at least 2,500 feet above the surface and in a climbing, wings level attitude. Single-piloted aircraft that are assigned operating altitudes below 2,500 feet should not be required to change frequencies or IFF codes until a level attitude and cruise configuration have been attained.

Position reports that pilots will be required to make to departure control will vary depending upon the weather, state of training, EMCON, and type of operation being conducted. The following reports are considered as minimum during IFR/night operations:

1. Outbound on assigned radial.
2. Popeye (with altitude).
3. On top (with altitude).
4. Kilo.

The degree of control exercised by CATCC concerning departures again depends upon existing weather conditions and is described similarly to arrivals.

1. Case I departure is VFR from takeoff through rendezvous.

a. On CVA's all fixed-wing aircraft proceed directly to a point at least 5 miles from the carrier at an altitude of 300-500 feet, and remain clear of the control zone. Rendezvous will be in accordance with ship/air wing/air group doctrine.

b. On CVS's all fixed-wing aircraft proceed 1 minute on the launch course, then execute a 40-degree right turn, remaining at or below 300 feet until at least 5 miles from the carrier, then proceed to their assigned areas.

2. Case II, VFR departure from the ship with a controlled climbout required.

a. CVA's. All fixed-wing aircraft will proceed straight ahead and maintain an altitude of 300-500 feet until 5 miles from the carrier. Jet aircraft fly a 7-mile arc to intercept their assigned departure radial. Propeller and turboprop aircraft fly a 5-mile arc to intercept their assigned departure radial. Such aircraft must remain VFR until established on the assigned departure radial.

(1) Jet rendezvous will be accomplished between 20 and 50 miles from the carrier. Propeller aircraft rendezvous between 10 and 50 miles. The rendezvous may be accomplished below or above cloud layers, at the flight leader's discretion, but will be on the left side of the assigned departure radial. The air wings/groups will normally prescribe their own VFR rendezvous doctrines.

(2) For jet and turboprop aircraft, the first aircraft of each flight will report to departure control passing 24,000 feet if not ON TOP. Unless operational necessity dictates otherwise, the departure controller will then direct pilots to climb and maintain the following altitudes in each sector or on the departure radial:

(a) First aircraft—29,000 feet.
(b) Second aircraft—27,000 feet.
(c) Third aircraft—25,000 feet.
(d) Fourth aircraft—23,000 feet.

If the aircraft are still "popeye" when the assigned altitude is reached, pilots will establish a nonstandard holding pattern between 40 and 50 miles out on the assigned departure radial and conserve fuel.

(3) For propeller aircraft, the first aircraft of each flight will report to departure control passing 7,000 feet if not ON TOP. Unless operational necessity dictates otherwise, the departure controller will then direct pilots to climb and maintain the following altitudes in each sector or on the departure radial:

(a) First aircraft—10,000 feet.
(b) Second aircraft—9,000 feet.
(c) Third aircraft—8,000 feet.
(d) Fourth aircraft—7,000 feet.

If the aircraft are still "popeye" when the assigned altitude is reached, pilots will establish holding on the outbound radial between 20 and 30 miles and conserve fuel.

(4) After the aircraft previously described in (2) and (3) report that they are

established in holding, departure controllers should issue clearance to proceed on the assigned mission if operationally required, or to continue holding until other returning flights have been recovered. When the returning flights have been recovered, the holding aircraft will be vectored under close control to their prebriefed marshal fix for recovery.

b. CVS's. A minimum departure interval of 30 seconds is utilized between aircraft. After takeoff, propeller aircraft climb straight ahead to an altitude of 300 feet until 5 miles out. Then they climb at 130 knots on the 5-mile arc until intercepting the departure radial and continue climb to assigned altitude. When pilots report KILO, the departure controller should execute a radar handoff to the CIC tactical controller. Mission unable aircraft will enter holding at the prebriefed departure fix and await instructions. Within the control area, aircraft will maintain the assigned departure altitude while outbound to the assigned area. CVS's operating jet and propeller aircraft would follow the same procedure as CVA for Case II departures under these conditions.

3. Case III. IFR at the carrier and a controlled climb required.

a. CVA's. A minimum departure interval of 30 seconds is utilized between elements (section or single aircraft) when instrument conditions exist. Jet aircraft climb straight ahead at 300 knots until 5 miles from the carrier. They then fly the 7-mile arc, climbing to intercept the assigned departure radial. Turboprop aircraft climb straight ahead at 165 knots to intercept the 5-mile arc and maintain an altitude of 1,000 feet until intercepting the assigned departure radial. Propeller aircraft climb straight ahead to 800 feet and fly the 5-mile arc maintaining 800 feet until intercepting the assigned departure radial. Jet rendezvous will be accomplished between 20 and 50 miles. If unable to reach ON TOP, aircraft will proceed as in Case II, unable to reach ON TOP.

b. CVS's. Propeller aircraft departures under Case III are the same as for Case II except that the aircraft will climb straight ahead to 500 feet using a minimum interval of 1 minute at departure. Jet aircraft departures are the same as for CVA Case III.

Helicopter Departures

Case I. Helicopters should clear the control zone as directed by the tower. When departing for operations within the control zone, they should remain under control of the tower or other designated controlling agency until clear of launching and recovering aircraft.

Case II and III. Whenever possible, helicopters should remain beneath the clouds. If unable to do so, they should proceed individually to prebriefed departure fixes. After takeoff, they should climb straight ahead to an altitude of 300 feet at 90 knots to intercept and fly the 3-mile arc to the assigned departure radial. The climb to departure altitude should be commenced upon reaching the departure radial.

Plane guard helicopters fly the 1-mile arc to intercept the plane guard pattern, remaining beneath the clouds. If unable to remain beneath the clouds, the plane guard helicopter should transition from the plane guard pattern to the helo marshal (fig. 7-7) under positive control of CATCC.

Helicopters proceeding to the screen should be switched to the tactical controller upon reporting KILO. If unable to perform the assigned misson, they should hold at the departure fix and await further instructions. When helicopters are assigned a search area toward the stern of the ship, they should be kept under close control by the departure controller until they clear the final approach sector and then be given to CIC via radar handoff. Helicopters should never be vectored across the bow when fixed-wing aircraft are being launched or recovered.

TANKER OPERATIONS

Tanker aircraft are assigned duties in support of the recovery of aircraft. Normally, a tanker that has just been launched will become the duty tanker for the recovery that follows immediately, provided that the tanker's store is operational. Those tankers which are known to have a good store and sufficient fuel to meet receiver requirements display a flashing green light.

A specific existing agency, for example departure control, is designated as tanker control

10853

and will have the responsibility of monitoring the following:

1. Tanker give-away fuel.
2. Tanker location.
3. Location and fuel requirements of the low state aircraft.
4. Coordination of the tanker and receiver rendezvous.

Duty Tanker Procedures

When VFR weather conditions exist (day and night), the oncoming duty tanker joins the offgoing tanker at 2,000 to 5,000 feet overhead the ship. The oncoming aircraft should have his store checked by, and receive the excess fuel from, the offgoing aircraft (referred to as Happy Hour). All tanker packages should be checked as soon as possible after launch by the offgoing tanker. If there is no offgoing tanker, then another aircraft should be used to check the tanker package.

Tanker control is advised when it has been determined that the new tanker's store is operational. During the time that one tanker is being relieved by another, both tankers should stay within 10 miles of the ship to be available for emergency tanking. When the relief process has been completed, the new duty tanker will advise tanker control of the amount of give-away fuel available. Give-away refers to the amount of fuel transferable based on scheduled recovery time.

The duty tanker orbits overhead the ship (within 5 miles) between 2,000 and 5,000 feet during recovery operations until the last jet aircraft is aboard. When the recovery is complete, the tanker will climb to the prebriefed altitude (usually 20,000 feet) and switch to the assigned frequency for control. Prior to the next launch, the duty tanker will descend to between 2,000 and 5,000 feet and check out the oncoming tanker.

When IFR weather conditions exist (day and night), tanking is accomplished 1,000 feet above the overcast, or between layers in VFR conditions. The tanker pilot should advise tanker control of the best altitude and position to conduct emergency tanking. Close radar control should be provided for tanker overcast penetrations. Tanker control must assist in positioning the tanker near a potential receiver and should keep the tanker informed of the potential receiver's position.

RENDEZVOUS PROCEDURE.—During VFR weather conditions (day and night), the duty tanker will HAWK (closely monitor) a particular aircraft that is a potential receiver. The tanker pilot is advised which aircraft is to be HAWKED, and he should take up a 2 o'clock position relative to the low state aircraft as it bolters or waves off. The low state aircraft is directed to rendezvous with the tanker, and the tanker will be switched to the low state aircraft's frequency at the appropriate time. The tanker pilot will report to tanker control when the receiver is engaged and taking on fuel, when the refueling has been completed, and the amount of fuel transferred.

When IFR weather conditions exist, tanker control will coordinate the tanker and receiver rendezvous.

DUTY TANKER PATTERN.—The tanker pattern is established as a racetrack pattern around the ship in VFR weather conditions. The downwind turn should be initiated as soon as the receiver is taking on fuel. The tanker should remain within 10 miles of the ship unless special circumstances exist. The downwind leg should be 3 to 5 miles abeam and tanking should be completed prior to reaching a point 6 miles astern to allow for pattern entry. If tanking is done above an overcast or between layers, the distance astern is increased to allow for normal descent and CCA pickup.

DIVERSION OF AIRCRAFT

The Air Operations Officer and the Air Officer are normally responsible for making the recommendation to the commanding officer when and which aircraft should and should not be diverted in the interest of safety of flight. The Air Operations Officers determines the condition of the navigation, communications, and lighting facilities of the divert field prior to the first night or IFR recovery.

CATCC and CIC must be alerted when an aircraft is approaching diversion state and they should be prepared to take control of the aircraft as soon as it is given a divert signal. When it is determined to divert an aircraft, the pilot will be given the name of the field, the magnetic heading, and distance to the field. A readback of diverting instructions from the

10829 10854

pilot or flight leader is mandatory. When appropriate, the pilot of the diverting aircraft is instructed to shift to a particular frequency for positive control while en route to the diversionary field. When positive communications have been established, additional items of information such as latest en route and field weather, altimeter setting, and position from which the diversion is being initiated are provided to the pilot.

If operating outside an ADIZ boundary, the CIC controller will provide the pilot with the necessary ADIZ information. The appropriate GCI site must be advised of the diverted aircraft's departure point, ADIZ penetration point, time of penetration, altitude, ETE, destination, and any additional information that may be pertinent to safety of flight. CIC will maintain a radar plot and radio monitor all diverting aircraft as long as possible and retain responsibility for the aircraft until positive radar handoff to GCI/ARTCC or other appropriate agency is accomplished.

Under IFR weather conditions, the pilot of a diverting aircraft must be instructed to shift to the appropriate FAA or other controlling agency frequency after the additional divert information has been issued. Once communications have been established with this controlling agency, the flight plan particulars should be furnished (by the pilot) including ADIZ penetration information for relay to a GCI site. If communications cannot be established, as is often the case, the pilot should file the flight plan information on the GCI common frequency.

The Air Operations Officer must insure that a divert flight plan is transmitted to the appropriate divert airfield, and similar information to the pertinent air defense system agency should an ADIZ penetration be involved. This is normally done on ship to shore radio circuits from the air operations office. The pilot should insure that an arrival time is filed and sent to the ship immediately upon landing. The Air Operations Officer is responsible for receipt of an arrival report on the diverted aircraft.

Squadron or Unit Commanders and the Air Operations Officer are jointly responsible for insuring that aircraft performance data pertinent to diversion of aircraft is available to and understood by personnel engaged in the control of aircraft.

CARRIER EMERGENCY PROCEDURE

From a control standpoint, carrier aircraft emergencies fall into three broad categories; i.e., communications failures, navaid failures, or other aircraft systems failures. The nature of some emergencies requires priority and/or diversionary measures. The ultimate resolution of these emergencies involves a command decision, based upon the type of emergency and weather conditions in the recovery area. It is imperative that CATCC collect every pertinent detail that might aid in the evaluation of an emergency and keep the command and other interested agencies properly informed.

Initial control responsibility for aircraft emergencies rests with the agency exercising control of the aircraft when the emergency occurs. Aircraft in a state of emergency within visual range of the ship will normally be controlled by the Air Officer. Outside the visual range of the ship, aircraft in an emergency will be controlled by either CIC or CATCC.

COMMUNICATIONS OR NAVAID FAILURE DURING AN APPROACH

Control of air traffic in the vicinity of a carrier, as well as ashore, during an emergency is based on anticipated pilot action. Therefore, the AC aboard ship must be alert for the following procedures a pilot may execute in the event an aircraft on approach experiences navaid or communications failure:

1. Aircraft alone.

a. If navigational equipment is available, lone aircraft will continue approach.

b. If all communications and navigational equipment is lost, the pilot will proceed as follows:

(1) The pilot may elect to continue the approach by dead reckoning. Having made this decision, he will continue DR until 2 minutes past his expected ramp time, and then fly the appropriate triangular pattern for lost communications, squawk emergency, and conserve fuel. If below the overcast, the pilot may elect to fly a search pattern to locate the ship.

(2) If the pilot elects to discontinue the approach, he will climb on final bearing

10856

10855

above the resonant frequency of channel 10 (104.5 mc), so the tank cirucit appears capacitive to that frequency.

The tank circuit has the same effect on frequencies ABOVE its resonant frequency that it has previously during pulse expansion—that is, it will delay these frequencies by an amount proportional to the amount of capacitive reactance the tank offers to that frequency. The 105-mc signal, being the farthest away from the f_0 of the tank, will be delayed the most (approximately 0.45-μsec).

The next frequency to arrive at the tank is slightly later in time and lower in frequency, and receives slightly less delay than did 105 mc. When 104.5 mc arrives (at T_0 plus 109.5 μsec), the tank simply passes it exactly as it is. The rest of the frequencies within the bandpass of channel 10 are lower than the f_0 and sees an inductive reactance. This advances these lower frequencies by an amount proportional to the X_L of the tank. The 104-mc signal, the lowest frequency within channel 10's bandpass, sees maximum inductance and is advanced approximately 0.45-μsec. The end result is that the bandwidth of frequencies of channel 10 (which was 1 μsec wide) is compressed to 0.1-μsec, and comes out of channel 10 at T_0 plus 109.45-μsec to T_0 plus 109.55-μsec. This is shown in figure 15-22.

The band of frequencies processed and compressed by channel 10 arrived at the receiver antenna from T_0 plus 100-μsec to T_0 plus 101-μsec. From T_0 plus 101 μsec to T_0 plus 102-μsec, the frequencies within the bandwidth

Figure 15-22.—Individual channel compression.

of channel 9 will be arriving at the receiving antenna. To get to the tuned tank of channel 9, they must pass through the 8-μsec delay line. Then, at T_0 plus 109-μsec, the first frequency for channel 9 (104 mc) will arrive. This frequency is higher than the resonant frequency (103.5 mc), so it will be retarded approximately 0.45-μsec, and will be reproduced in the output of channel 9 at T_0 plus 109.45-μsec. The lowest frequency to channel 9 (103 mc) sees maximum inductance and will be advanced approximately 0.45 μsec. Channel 9 will produce its output from T_0 plus 109.45 μsec to T_0 plus 109.55 μsec, or during the same time channel 10 was producing an output.

This process continues as each one of the channels receives its band of frequencies 1 μsec apart in time, but produces its output at the same time as each of the other channels. Finally, at T_0 plus 109-μsec, the first frequency to pass through channel 1 arrives at the receiving antenna, and is felt directly on the tuned tank in channel 1 since channel 1 has no delay line. Channel 1 then produces an output at the exact same time as the previous nine channels.

COMBINED OUTPUT OF THE MATCHED FILTER.—The output circuit of each individual channel is fed into summing amplifiers where all 10 outputs are combined. Because each channel produces an output at exactly the same time, and for exactly the same time duration, all 10 outputs add directly, and appear at the output of the summing amplifiers as one pulse 0.1 μsec in duration. The entire 10-μsec return echo has been compressed to 0.1-μsec, and is now ready to be detected and sent to the indication devices.

The ratio between the pulse width of the transmitted pulse and the returned compressed target echo is expressed as the compression ratio. It is determined as follows:

$$\text{Compression ratio} = \frac{\text{pulse width of expanded pulse}}{\text{pressed width of compulse}}$$

The compression ratio of the radar being discussed is:

$$\text{Compression ratio} = \frac{10\text{-}\mu\text{sec}}{0.1\text{-}\mu\text{sec}} = \frac{100}{1} = 100{:}1$$

This expression is considered a figure of merit for a pulse compression type radar.

1083

heading to VFR conditions and expeditiously join up on the tanker or other available aircraft. If unable to join on another aircraft the pilot will fly two left-hand triangles, conserving fuel. Depending upon weather at the divert field and fuel state, the pilot may elect to proceed directly to the divert field after having climbed out on the final bearing heading.

(3) Helicopters may continue descent to 300 feet, proceed by DR until 2 minutes past individual expected ramp time, and then fly the appropriate triangular patters for lost communications, squawk emergency, and conserve fuel.

2. Aircraft in company. An aircraft with navigation and/or communications failure in the company of an escort aircraft with navigation and communication equipment in working order will be handled as a single aircraft in the recovery procedure. The escort aircraft as flight leader will visually communicate with the distressed aircraft. When the distressed aircraft can safely continue the approach, he will acknowledge a lead change and continue to a landing. The escort aircraft will then assume the position of a safety wingman, as necessary until the distressed aircraft is recovered, and then continue normal procedures for his own recovery.

LOST COMMUNICATIONS DURING AN INSTRUMENT DEPARTURE

If communications are lost during an instrument departure, the pilot should squawk modes II and III and IDENT once every minute for 5 minutes. Climbout should be continued to the assigned emergency altitude and distance on the assigned departure radial unless a different altitude assignment by air traffic control has been acknowleged. The pilot should hold at this point for 30 minutes and then proceed to emergency marshal and commence approach at the emergency expected approach time. The pilot should proceed to emergency marshal by arcing counterclockwise AROUND the ship, climbing or descending to arrive at emergency marshal at emergency altitude. If under VFR weather conditions when communications are lost; pilot should remain VFR and return to the ship.

EMERGENCY FOLLOWING NIGHT/IFR LAUNCH

Should an aircraft have an emergency following a night/IFR departure and require an immediate landing, the departure controller should provide vectors until the final controller has acquired the aircraft on radar. Every effort should be made to retain the aircraft on the departure frequency until it is safely aboard. Pri-Fly and the LSO must be advised immediately of the emergency and the control frequency.

When feasible, aircraft with emergencies which do not require immediate recovery should continue the departure until cleared into the marshal pattern.

BASIC PROCEDURES

Controllers must be familiar with and alert for conditions and pilot actions which indicate communication or navigation failures. Basic control procedures which may be performed, depending upon the situation, include the following:

1. Attempt to establish communications with and control of the aircraft.
2. Vector the aircraft as appropriate.
3. If unable to communicate with the aircraft in difficulty, attempt the following:

a. Identify it on radar and maintain a track.

b. Vector available aircraft to join up if practicable.

c. Alert the CATCC watch officer and Pri-Fly.

d. Broadcast instructions and essential information in the blind.

10856

10856

CHAPTER 8

ADMINISTRATION

There are many definitions of administration. Each one is probably perfectly valid and incorporates the concept of getting things done through planning, supervision, direction, and coordination of human activity. Using this concept as a basis, administration may be thought of as a means by which the ATC/OC division accomplishes its mission.

The basic objective of administration is very broad; namely, effective management. Its major operational objectives include the following:

1. To obtain the best qualified people for the work to be done and to insure that the best use is made of their capacities in the organization.
2. To establish policies and working conditions that will develop and maintain the best work interest, satisfaction, and performance.
3. To assure value for value in expenditure of funds and quality of performance commensurate with cost.

It is immediately apparent that administration is not a specialized field, but is a responsibility and function of every supervisor.

When a supervisor is given a task, he first should determine the objectives of the task. He should then organize his personnel and material by assigning and coordinating such specific duties and functions as are necessary to reach the objective. Finally he should administer the organization by providing leadership, direction, coordination, and control to guide the organization toward the accomplishment of the objective. This would indicate, then, that organization is the machinery of administration.

ORGANIZATION

Organization is the means by which management plans, directs, coordinates, and controls operations and activities. It is the division of work into logical groupings of functions and the establishment of channels of authority, communications, and control between the personnel assigned to the various functional groupings.

Our fast moving world with its scientific and technological advances and the role of our nation in international affairs have thrust upon the United States tremendous responsibilities and challenges. The organization of the Department of Defense is the method by which the efforts of military and civilian personnel are systematically coordinated to shoulder the responsibilities and meet these challenges.

Senior AC's deal not only with other divisions and departments within their own activity, but also with various commands and offices of the Department of the Navy.

For a review of the organization of the DOD and Department of the Navy down through the operating forces level, refer to Military Requirements for Petty Officer 1 & C, NavPers 10057-C.

ACTIVITY ORGANIZATION

NavAir Instruction 5450.89 sets forth the standard structure for the internal organization of field activities under NavAirSysCom management control.

The purpose of this guide is to assist each activity in establishing and maintaining its organization so that the assigned mission can be accomplished in the most effective and efficient manner.

The formal organization structure of an activity is determined by the functions to be performed, the personnel available to perform

108801

10857

AC. 16

Figure 8-1.—Structural/functional chart of an Air Operations Department.

10858

them, available material resources, and the management policies and philosophies of the management command and higher levels of authority.

Each activity will maintain an organization manual, in current status, in accordance with the standard organization guide. This manual can be a valuable tool to senior AC's in determining lines of authority and responsibility, and for assistance in indoctrinating new personnel.

The top level of organization is the activity commanding officer, variously titled Commander, Commanding Officer, Officer in Charge, etc. The following nomenclature in descending order are the components of naval air station organization at the lower levels:

1. Department.
2. Division.
3. Branch.
4. Section.
5. Unit.
6. Subunit.

AC's are normally assigned to the Air Operations Department of a naval air station. Figure 8-1 is a combined structural/functional chart of an Air Operations Department with the various exceptions noted.

Figure 8-2 is an example of an OC division organizational chart aboard ship. Although shipboard organization is not described in the Standard Organization Manual, this chart indicates the chain of command applicable to AC's aboard ship at the division level.

Every individual appointed as head of a component of organization (department, division, branch, section, etc.) is inherently responsible for the effective and efficient performance of that portion of the activity's work assigned to his component. He is also responsible for compliance with applicable directives from higher authority; leadership, training, safety, and supervision of subordinate personnel; and proper use, care, and custody of equipment, facilities, and materials provided.

GENERAL DIVISION ADMINISTRATION

The size, mission, personnel complement, and the service provided by the local ATC/OC division vary widely throughout the Navy. The organization to which the AC1 or ACC is assigned is probably already well established. If not, then the supervisor is faced with a greater challenge. If so, changes are continuously required for improved applications or directed procedural or equipment modifications.

THE NAVY DIRECTIVES SYSTEM

The Navy Directives System, which provides a uniform plan for issuing and maintaining directives, was placed in effect 1 July 1952. The basic system has been retained since that date; however, improved procedures to increase its usefulness have been incorporated.

When directed by the Chief of Naval Operations or the Chief of the cognizant bureau or systems command, commands in the Operating Forces and activities in the Shore Establishment will install the system following the standards set forth in SecNav Instruction 5215.1 (Series), the Navy Directivies System. The most significant benefits derived from this System are as follows:

1. The Navy-wide use enables each activity which receives directives to:

a. Effectively group the directives on any specific subject and relate directives on the same subject with other materials.

b. Have an easy method for filing directives and describing them as references.

c. Differentiate between directives of a continuing nature and those of brief duration.

d. Obtain copies of instructions to replace lost or damaged copies, or obtain complete sets of instructions upon reactivation or commissioning.

e. Determine periodically by use of checklists the current status and the completeness of its set of directives.

f. Determine by the use of subject indexes what directives are in effect on a subject.

2. Each naval activity which issues directives is able to:

a. Reduce the number of directives in effect by systematically consolidating instructions which cover the same subject, by eliminating instructions which duplicate, overlap, or conflict, and by promptly canceling obsolete directives.

00801 10859

AC.17

Figure 8-2.—OC division organization.

b. Improve the adequacy and coverage of instructions and identify gaps in policy and procedures so that directives can be issued to cover necessary subjects.

c. Eliminate duplicate writing, printing, and distributing operations.

d. Insure that recipients are sent only those directives which pertain to their operations.

e. Improve general administration by using a uniform system which includes reference aids for recipients of directives.

Directive

A directive is an Instruction or Notice that prescribes or establishes policy, organization, conduct, methods, or procedures; requires action or sets forth information essential to the effective administration or operation of activities concerned; or contains authority or information that must be promulgated formally.

Instruction

An Instruction is a directive containing authority or information having continuing reference value or requiring continuing action. It remains in effect until superseded or otherwise canceled by the originator or higher authority.

Notice

A Notice is a directive of a one-time or brief nature with self-canceling provision that has the same force and effect as an instruction. Usually it remains in effect for less than 6 months, but is not permitted to remain in effect for longer than 1 year.

Alphabetical Subject Indexes

The Navy Directives System, Consolidated Subject Index, consisting of unclassified instructions originating in various bureaus and offices and promulgated by the Navy Publications and Printing Service, is issued on 30 June. (Quarterly supplements are also issued.) This Index is to assist addressees in identifying departmentally originated instructions on any desired subject. Each current edition provides an alphabetical guide to the subject matter of all unclassified instructions by components of the Navy Department.

10860

Directives issued by components of the Navy Department are addressed to many different distribution lists. Therefore, no specific activity receives all the instructions included in this Index. However, since originators determine distribution on a need-to-know basis, each activity receives or should receive instructions on subjects with which it is concerned. An activity may determine whether it is an addressee on a particular instruction by referrring to the current Navy Directives System, Consolidated Check List.

Numerical Checklists

The Consolidated Check List is prepared annually on 30 June and should be retained for use in conjunction with subsequent quarterly supplements. These numerical checklists are issued to only those units and facilities listed in Part 1 and Part 2 of the Standard Navy Distribution List (SNDL) in checking their master sets of instructions. Checklists cannot be used by activities not on the SNDL and cannot be used by activities not maintaining the master set of directive binders for the cognizant command.

Standard Navy Distribution List

The Standard Navy Distribution List is published to provide for the proper addressing and distribution of mail to all activities of the Naval Establishment, and to provide a condensed procedure for permitting circular distribution of correspondence.

The Standard Navy Distribution List is published in two parts. Part 1 is a Confidential, nonregistered publication entitled Standard Navy Distribution List (Operating Forces of the Navy and Unified Commands). Part 2 of the SNDL contains the Catalog of Naval Shore Activities. This part (nonregistered and unclassified) contains the official list of shore activities of the Naval Establishment. The term "shore activities of the Naval Establishment" includes activities of the Shore Establishment and shore activities assigned to the Operating Forces.

SECURITY FOR CLASSIFIED INFORMATION

In the daily work routine, Air Controlmen learn information and strategic data of importance to the military and the nation. Some of the information carried in messages handled by Air Controlmen, if available to an enemy, would reveal facts relating to the strength and movements of naval aviation. Furthermore, an Air Controlman uses official documents and publications which relate to such communications matters as procedures, frequencies, call signs, etc. Their contents must also be protected.

The following discussion is generalized and is not intended to serve as a complete reference of security matters for the Air Controlman. If the leading Air Controlman needs further references on security matters, he should refer to chapter 15, U.S. Navy Regulations, 1948, and to OpNav Instruction 5510.1 (Series).

Material considered to be of such importance that its disclosure to unauthorized persons would be detrimental to our defense effort is said to be classified. Classified material is any matter, document, product, or substance on or in which classified information is recorded or embodied. Three general categories of classification are authorized for such material. They are, in descending order of importance, TOP SECRET, SECRET, and CONFIDENTIAL.

Top Secret

Top Secret material or information is that of which the defense aspect is paramount, and the unauthorized disclosure of which would result in exceptionally grave damage to the Nation. Such grave damage might consist of, but is not limited to, either of the following statements:

1. Leading to a definite break in diplomatic relations affecting the defense of the United States, an armed attack against the United States or her allies, or a war.
2. The compromise of military or defense plans, or intelligence operations, or scientific or technological developments vital to the national defense.

Particular attention should be paid to the words "grave," "war," "definite," "attack," and "vital." They are used as words of emphasis. Top Secret material is of tremendous importance to our country.

10861

Secret

The classification Secret is limited to defense information or material the unauthorized disclosure of which could result in serious damage to the Nation. Its disclosure might jeopardize the international relations of the U.S., endanger the effectiveness of a program or policy of vital importance to national defense, compromise important military or defense plans or technological developments, or reveal important intelligence operations.

Confidential

The Confidential classification is limited to defense information or material, the unauthorized disclosure of which could be prejudicial to the defense interest of the Nation.

The Term Confidential—Modified Handling Authorized may be used to identify certain categories of Confidential information requiring lesser security safegaurds in stowage and transmission.

Types of Security

Provisions for safeguarding classified matter are based on law and executive order. Those of interest to Air Controlmen may be grouped into three categories: COMMUNICATIONS SECURITY, PHYSICAL SECURITY, AND PERSONAL CENSORSHIP.

COMMUNICATIONS SECURITY.—Communications security prevents the enemy from obtaining information from United States or allied communications. Communications security is subdivided into two categories: cryptographic security and transmission security.

Cryptographic security is designed to thwart enemy efforts to obtain intelligence through cryptanalysis and the study of traffic trends. It is the science of cloaking information in codes and ciphers. A code is a system whereby words, phrases, numbers, or syllables are replaced by numbers, letters, or code words. A cipher is a system in which individual letters of a message are replaced, letter for letter, by other letters rather than by complete words, phrases, or numbers.

Transmission security is that component of communications security which results from all measures designed to protect transmissions from interception, traffic analysis, and imitative deception.

Any time a message leaves the originator and is sent on its way to the addressees it is transmitted. It does not matter whether the message goes by courier, radio, wire, mail, or visual means; it must be safeguarded in transit. The means of protection vary, but the purpose, in every case, is two: to keep the information out of the hands of those not authorized to have it, and to prevent our own communications from being turned against us. The means of transmission of messages in order of security are as follows:

1. Messenger authorized to carry classified material.
2. Registered mail.
3. Approved wire circuits.
4. Ordinary mail.
5. Nonapproved wire circuits.
6. Visual means.
7. Sound systems.
8. Radio.

However, all Air Controlmen must consult the Confidential publication ACP 122 for the final authority for transmission security.

PHYSICAL SECURITY.—Measures designed to keep classified information from physically coming into the possession of persons not authorized to have it come under the heading of physical security. Physical security is based on two principles: (1) constant surveillance of classified material when in use, and (2) proper stowage when not in use. The classification of material has a bearing on the number of authorized personnel entitled to have access to the material, and each classification has its own stowage and transmission requirements. Air Controlmen having access to classified matter should keep in mind that physical security precautions must be observed in handling, distributing, accounting for, and storing such material.

PERSONAL CENSORSHIP.—Every individual in the Navy is a censor in that he or she is expected to be discreet in his or her own utterances and writings. The only safe conversational policy to follow when off duty is to say nothing about official matters to anyone. One should plead ignorance of the subject or make it plain they do not wish to talk shop. Personal censorship is most abused through such means as the following:

10862

1. Loose talk in public places.
2. Personal correspondence.
3. Telephone conversations.
4. Diaries.

These precautions do not guarantee protection nor do they attempt to meet every conceivable situation. However, all Air Controlmen who adopt a commonsense outlook in addition to knowledge of the few basic regulations can solve most of the personal censorship problems involved in security.

Security Clearances

No one may have access to classified matter without proper clearance. If your duties as an Air Controlman require you to use classified publications and documents, the commanding officer is authorized to grant this clearance after ascertaining that you are trustworthy, discreet, and of unquestionable loyalty.

Clearance to handle Confidential information may be based on an unblemished service record and the good opinion of your officers. Clearance to handle Top Secret and Secret material can be granted only after an additional check of BuPers records and an investigation by the Office of Naval Intelligence. A notation of a man's clearance must be made in his service record.

Need-To-Know Concept

The need-to-know concept requires that only those persons whose official military or other governmental duties require it are allowed access to any piece of classified information. The responsibility for determining whether a person's duties require that he possess or have access to classified information and whether he is authorized to receive it rests upon each individual who has possession, knowledge, or command control of the information involved and NOT upon the prospective recipient. This principle applies whether the prospective recipient is an individual, a command, a defense contractor, another Federal agency, or a foreign government.

A need to know is recognized as being established when (1) the disclosure is necessary in the interests of national defense; (2) there must be evidence, from the position, status, duties, and responsibilities of the applicant, that he has a legitimate requirement for access to the classified information in order to carry out his assigned duties and responsibilities; (3) there is no other equal or ready source of the same classified information available to him; and (4) the applicant is or can be appropriately cleared for access to the degree of classified information involved and is capable both physically and mentally of providing the degree of protection which that information requires.

Control of Top Secret Information

All individuals having knowledge of Department of Defense information classified Top Secret must be identifiable at all times. Each organization or office originating or receiving information classified Top Secret must maintain a list of those persons within such organization or office having access to Top Secret information. Access lists of recipients of Top Secret information will not be forwarded to the office originating the information except upon request.

Upon preparation or receipt of Top Secret information, each originator or recipient must keep a record of the names of all persons, including stenographic and clerical personnel, who are afforded access to the Top Secret information originated or received.

Upon origination or receipt of Top Secret material, a disclosure record form must be attached immediately to the material and any individual gaining knowledge of the contents thereof must affix to the form his name, the name of the activity, and the date of access. If an individual's signature is used and is not clearly legible, the name must also be printed.

Disclosure record forms must not be detached from the Top Secret material upon which they are placed unless such material is transmitted to another activity for retention. When such forms are detached, they must be retained locally for a period of at least 1 year, in accordance with SecNav instructions.

Mail rooms, file rooms, communication and message centers, and printing and reproduction activities engaged in processing large volumes of Top Secret material need not require assigned personnel to individually sign the disclosure record form if access to such areas is limited to permanently assigned

10863

personnel and if such individuals are identifiable by roster as having access on any given date.

Oral discussions within committees or at conferences involving the disclosure of Top Secret information are also subject to accountability requirements. The minutes of the conference or meeting, showing a complete listing of all persons present and giving a summary of the information discussed, are considered to be a sufficient record for purposes of accountability.

Control of Copies and Extracts

Material classified Top Secret and Secret originating outside the Department of Defense must never be reproduced without the consent of the originating agency.

Originators of Top Secret documents must insure, at the time of issuance, that all copies of each document are serially numbered and limited as to reproduction.

Originators of classified material other than Top Secret, including RPS-distributed nonregistered publications, may limit the reproduction or extracting thereof as necessary. In no event, however, may classified material be reproduced or excerpted without the approval of competent authority.

When classified documents are reproduced on office copying equipment, care must be taken to see that the classification marking is clearly legible on each finished copy. Office copying equipment does not always clearly reproduce all colors of ink or marginal images.

Destruction of Classified Documents

Top Secret, Secret, and Confidential material may be destroyed by burning, pulping, pulverizing, or shredding, provided that the destruction of the classified material is complete and that reconstruction is impossible.

Destruction of classified material must be accomplished in the presence of two witnessing officials. A witnessing official must be a commissioned officer, a warrant officer, an enlisted man E-7 or above, or a United States civilian employee GS-7 or above. If none of these categories is available, a mature and reliable enlisted man E-5 or E-6 or a U.S. civilian employee in grade GS-5 or GS-6 may be designated as a witnessing official. All persons witnessing the destruction of classified material must have a security clearance at least as high as the category of material being destroyed, and they must be thoroughly familiar with the regulations and procedures for safeguarding classified information.

When appropriate, Certificates of Destruction must be prepared and signed by the witnessing officials. Witnessing officials must observe the complete destruction of the classified documents. Residue must be checked to determine if destruction is complete and reconstruction is impossible. When classified material is being burned, witnessing officials must take precautions to prevent portions of the classified material from being carried away by the wind or draft. When classified material is being destroyed by other methods, precautions must be taken to see that no scraps of undestroyed material are carried away by the wind.

Destruction of Classified Equipment

When it is necessary to dispose of equipment that must remain classified, destruction must be accomplished by any means that will prevent recognition and reconstruction. Jettisoning of classified equipment in water of sufficient depth to preclude any possibility of recovery may also be employed.

Record of Destruction

An accurate record of destruction of classified material is as important as its destruction. Proper accounting procedures, together with accurate records of destruction, provide official information as to the status of classified material.

A Certificate of Destruction of nonregistered Top Secret and Secret documents must be prepared. The certificates must be retained for a period of 2 years by the command destroying the material. Each certificate must provide complete identification of the material destroyed and the date of destruction, and it must be signed by the officer authorizing the destruction and by the witnessing officials, one of whom may be the official authorizing destruction.

In the case of Secret documents only, use of routing sheets, mail logs, or other similar

10864

administrative records in lieu of a Certificate of Destruction is authorized, provided that all necessary information (complete identification of the material destroyed, date of destruction, and signatures of the two officials, one of whom is to be the official authorizing destruction) is included. A Certificate of Destruction must be signed by witnessing officials when the material has actually been destroyed or when torn and placed into waste bags for central disposal.

Certificates of Destruction must be prepared for all classified equipment destroyed. The certificate must be retained for a period of 2 years by the command destroying the equipment, and a copy of the certificate must be forwarded to the technical bureau, office, or command responsible for procurement of the equipment.

Emergency Destruction

Commands located outside the fifty United States must include in their destruction plans provisions for an emergency involving the danger of capture of classified material. In an emergency involving the danger of capture of classified material, the importance of beginning its destruction sufficiently early cannot be overemphasized. The consequences of such destruction would be relatively unimportant when measured against the possibility of compromise through capture. Destruction plans of each activity will require of personnel at all levels the highest degree of individual initiative practicable in preparing for and in actually commencing the required destruction. Particular care should be taken to indoctrinate all personnel to insure their understanding that, in such emergencies and when required, they must initiate necessary destruction under the plan without waiting for specific orders. Lists must be prepared which show the locations of classified material, personnel responsible for the destruction, and the recommended place and method of destruction.

Priority for Emergency Destruction

In general, emergency destruction of classified materials should be carried out in the following order:

1. Classified communication material. Insofar as humanly possible, cryptomaterial must not be allowed to fall into enemy hands. Therefore, cryptographic material has the first priority. Noncryptographic communications material has the second priority; destruction should begin with the highest classification and work down to the lower classifications.

2. Other classified material. Emergency destruction of other classified materials must be carried out in order of priority, as follows:

a. Classified material pertaining to current and future plans and operations.

b. Classified material pertaining to standing operating or tactical procedures.

c. Equipment of a classified nature, together with pertinent technical, descriptive, and operating instructions.

d. Remaining classified material, with the order of destruction beginning with the highest classification and working down to the lower classifications.

Accessibility for Emergency Destruction

Classified material must be readily accessible at all times for emergency destruction by assigned personnel. When provisions in shipboard emergency destruction plans include jettisoning publications as a means for emergency destruction, document sinking bags are to be available for this purpose.

Material to be destroyed first must, when practicable, be marked in a distinctive manner and stowed in the most accessible location.

Keys and safe combinations to spaces where classified material is stowed may be kept in designated locations, safeguarded by proper security arrangements.

Local Printing, Duplication, and Reproduction of Classified Material

From a security point of view, the printing, duplicating, or reproduction of classified material poses many problems. It contributes to the increasing volume of classified material; it permits quick and easy production of uncontrolled material containing classified information; the equipment or processes require care for special procedures to prevent or eliminate latent impressions or offset versions of the classified material; and a quantity of excess and waste material is produced which can also contribute to the compromise of the classified information.

10865

During this process of pulse compression, some apparent amplification occurs across the matched filter. This is because of the energy content and time duration of the returned echo. The 10-μsec pulse arrives with a certain volt/amps energy content, but it is compressed in time down to a pulse of 0.1-μsec. Assuming none of the energy content was lost across the matched filter, the same amount of energy must still be present in the compressed pulse. If the pulse width narrows, the amplitude of the compressed pulse will increase. This increase is the same as the compression ratio. In the radar under discussion the pulse is compressed by a ratio of 100:1, so the amplitude of the compressed pulse is 100 times larger than the amplitude of the received target return, and still contains the same energy content.

It must be noted that in a practical radar using pulse compression, it is very difficult to get the returned energy compressed back to the same pulse width that was used in the pulse expansion sequence. As previously, there are many thousands of frequencies, each different by one PRF, in the transmitted pulse. Each of these frequencies bears a very definite time/phase relationship to each other. To compress the returning echo back to the original pulse width, each one of the frequencies must be present, and must still bear the exact same time/phase relationship that it did upon leaving the transmitting antenna. Due to atmospheric conditions and waveguide vibration, some phase modulation occurs between pulse expansion and pulse compression. Some of the frequencies will be changed, so it will not be easy to reconstruct the original pulse. In the radar under discussion, typically the 10-μsec returned echo is compressed into a 0.2-μsec pulse, for a compression ratio of 50:1. This means that if the entire energy content is maintained across the filter, the amplitude of the compressed target video would be 50 times larger than the amplitude of the returning echo.

SIGNAL-TO-NOISE RATIO

The noise which might exist in the band of frequencies covered by the radar are at random frequencies and bearing random phase relationships to each other, and to the returning target echo. Any of these frequencies which exist within the bandpass of the matched filter passes through the filter, but are not affected by the filter. That is, they are neither expanded nor compressed because of their random relationship, so they emerge at the same amplitude at which they went in while the return echo emerges enlarged in amplitude by the amount of the compression ratio. Radars using pulse compression are generally considered to have an increase in the signal-to-noise ratio across the matched filter approximately equal to the compression ratio. This is in addition to the signal-to-noise ratio increase which might be gained by using suitable receiver input amplifiers.

ECM CONSIDERATIONS

As was previously stated, it is very difficult to jam a pulse compression type radar. This is primarily because of the characteristics of the matched filter. To overcome the target video noise jammers would have to produce enough noise signal so that the noise at the receiver antenna would be greater than the returning target echo by the amount of the compression ratio. This is easily eliminated by insertion of circuits between the antenna and matched filter which automatically reject abnormally large signals. This method is currently in use in certain long range search radars in operation with the fleet. Repeater jammers, to override the actual target return, would have to generate a spectrum containing exactly the same frequencies, each bearing the exact same phase and time relationships as that of the transmitted pulse. Even if this were possible (some types of ECM equipments simply amplify whatever their antennas receive), the ECM signal would be rejected since it would be larger in amplitude than the valid received target return. This repeater jammer could have no more delay between the time it received the transmitter's signal and the time that it retransmitted this same amplified signal than the time duration of the compressed pulse as it comes out of the matched filter. When the delay is greater than the pulse width of the compressed pulse, the indication device (computer) would see two distinct returns. One would be the target, and the other would be the ECM signal. Even if the delay was less than the pulse width of the compressed pulse, the computer would still see the target return first, then a sudden increase in amplitude as the ECM signal came through. The computer would automatically reject ECM return,

1084

Because of these problems, local commands must require close supervision and careful control of all reproduction facilities under their jurisdiction. Of particular importance is the need for controlling and supervising the use of office copying machines for the printing duplication, or reproduction of classified material and to assure the proper recording and safeguarding of the classified material reproduced by such means. In no event, however, must classified material be reproduced without the approval of competent authority.

When authorized by competent authority, classified material may be produced or reproduced. The number of copies made should never exceed that required to meet a known need.

Classified material produced or reproduced by any means must be recorded in accordance with the requirements of the Security Manual. Samples, waste, or overruns resulting from the reproduction process must be safeguarded in accordance with the classification involved and must be destroyed promptly as classified waste.

When classified material is reproduced, the reproduced material must be marked with the classification and other special markings which appear on the original material from which copies or reproductions are made.

When thermal copy paper is used to reproduce documents upon which classified information has been recorded, only Type I (back coated) thermal copy paper must be used. When slip sheets are placed between the diazo process film sheets in the reproduction process of classified information, the slip sheets must be handled as classified waste.

FILING AND DISPOSITION OF RECORDS

The main objective of any filing system is to insure ready location of any correspondence with a minimum amount of effort and loss of time. As a leading petty officer of an ATC/OC division, the AC1 or Chief may be responsible for establishing and/or maintaining an adequate filing system for the division.

Details of file arrangement within any activity depend upon the mission of the activity and on the volume of official correspondence generated or received. There is no limit to the possible expansion under the Navy subject classification system, yet the system is equally adaptable to the needs of small offices. Files of the components of the Navy Department, for instance, occupy hundreds of cabinets; those of a division office may be kept in one or two cabinets. Yet the same general headings are used for both. The difference lies in the number of subdivisions under each major group.

Navy Filing System

The Navy filing system (used by the entire Navy) is the Standard Subject Classification System for the filing of records, correspondence, and other documents. This system is set forth in SecNav Instruction 5211.3 (Series).

The standard subject classification numbers (outlined in SecNav Instruction 5211.3 (Series)) used in the Navy for filing all correspondence and directives consist of 13 major subject groups. Each of these major subject groups is designated by a 4- or 5-digit numeric code. These major subject groups are as follows:

1000 Series	Military Personnel
2000 Series	Communications
3000 Series	Operations and Readiness
4000 Series	Logistics
5000 Series	General Administration and Management
6000 Series	Medicine and Surgery
7000 Series	Financial Management
8000 Series	Ordnance Material
9000 Series	Ships Design and Ships Material
10000 Series	General Material
11000 Series	Facilities and Activities Ashore
12000 Series	Civilain Personnel
13000 Series	Aeronautical Material

Small activities may adapt this sytem to their needs by preparing file folders for a minimum number of major subjects and arranging material within these folders according to the classification number assigned. Files may be expanded by adding more file folders as required. The file numbers originally assigned to the records remain pertinent and need not be changed. This makes expansion logical and easy. Large activities may adapt this filing

10866

system to their needs by preparing folders not only for the major subject groups but also for the primary and secondary groups.

The 13 major subject groups are subdivided into primary, secondary, and sometimes tertiary breakdowns. Primary subjects are designated by the last three digits of the major subject group numeric code. For example, the major subject of General Administration and Management, coded 5000, is subdivided into primary groups as follows:

5000 . . . . . General Administration and Management
5200 . . . . . Management Improvement
5300 . . . . . Personnel
5400 . . . . . Organization, Function, Status, etc.

Primary subjects are subdivided into secondary subjects by the last two digits of the numeric code. Tertiary breaks are indicated by the final digit. For example:

5200 Management Improvement
5210 Office Methods and Records Management
5211 Files and Records Systems

Additional information pertaining to classifying and filing correspondence and other documents by subjects may be found in SecNav Instruction 5211.3 (Series).

Establishment and Maintenance of Files

The following are factors contributing to the establishment of an efficient filing system:

1. Organization of a correct system.
2. Setting up correct file subjects in folders.
3. Correct classification of all incoming and outgoing correspondence.
4. Modification of the system as required.
5. Thorough indoctrination of personnel maintaining the file.

With a filing system correctly established, it is possible for anyone with a general knowledge of the Navy filing system to locate a particular piece of correspondence speedily and conveniently.

Filing equipment will vary depending upon needs of the division. Some of the most common are visible files and file drawer cabinets. The visible files are those in which cards, sheets, or strips of paper are arranged so that the margins can all be seen at once. These are frequently used to file AC data cards, for instance. The file drawer cabinet is used extensively for general filing purposes. It uses standard size filing folders with tabs for printing subject classification numbers to provide for visual sighting and easy location. (See fig. 8-3.)

How important are the records of the division's files? Important enough that Congress has passed laws governing their disposition and fixing penalties for their unauthorized destructtion.

Though sometimes monotonous, all tasks connected with files, including their disposition, must be taken seriously. Decisions whether to save or not to save cannot be avoided by simply saving everything. Sooner or later, filing cabinets become overfull and something has to be done. The key to the filing is to be able to tell what should be held in the files and for how long, and what should, or must, be destroyed or transferred for preservation.

Basic Government legislation covering records disposal defines Government records essentially as follows: All documentary material, including books, papers, maps, and photographs, made or received by an agency of the U.S. Government in connection with the transaction of public business and appropriate for preservation.

Navy Regulations defines Navy records as "Copies of all official correspondence sent and the originals of all official correspondence received, and such other correspondence as will or may become the subject of future reference or action." Additionally, official correspondence is defined as "All recorded communications sent or received by a person in the Naval Establishment in the execution of the duties of his office." Nonrecord material, then, may be defined as any material which serves no documentary or record purpose or, in other words, it is material that just is not worth keeping except for a limited time.

It is quite possible that very little of the material in the division office files would be classified as official records. It is not always possible to draw a distinct line between record and nonrecord material and apply a hard and fast rule. The disposition of the majority or records that the ATC/OC division would keep are referenced in official instructions.

10867

AC.233

Figure 8-3.—Visible files and file drawers.

10868

The following is a partial listing of logs and records common to air traffic control. The complete Navy system of records disposal is found in SecNav Instruction 5212.5 (Series).

1. Traffic control records relating to the internal control of air and space traffic and records relating to the supervision of clearance and other traffic control records—retain for 6 months.

2. Operations logs accumulated by the operations department of flight activites including control tower records—retain for 6 months.

3. Daily flight logs of visiting aircraft—retain for 6 months after date of last entry or after log is filled.

4. Aircraft clearance and arrival reports (progress strips)—retain for 3 months.

5. Clearance and weather forms (DD-175)—retain for 3 months. (OpNav 3710.7 (Series).)

NOTE: By agreement between FAA and DOD, military flight plans filed directly with FAA FSS's will be retained by them for 15 days and then forwarded to the home station indicated on the flight plan. Flight plans forwarded to naval shore installations by FSS's are retained in the operation department files for a period of 3 months after which they may be destroyed.

6. Correspondence, copies of reports, and other records relating to the internal operation and administration of air and space traffic—retain for 2 years.

7. Weight and balance clearance form (DD-365F)—retain originals 3 months.

These records are considered temporary and should be destroyed after the prescribed retention period.

There are two ways that records which have outlived their current value may be disposed of: (1) local destruction, or (2) transfer for later destruction or, if records are permanent, for preservation. To insure that handling of records is consistent and is not left to chance one officer is usually assigned the duty of coordinating all records disposal aboard an activity, either ship or station. This officer would then take charge of the physical dispostion of all official records that have been designated for either transfer or destruction. Most unclassified material in the division files would not require transfer but is of the type that may be destroyed in the office. Classified items must be destroyed by burning in accordance with current security regulations. At sea, unclassified records as well as those classified should be burned.

The General Services Administration is responsible for general procedures, both for disposal of Federal Government records and for reproduction of them. Seventeen Federal Records Centers have been established at locations conveniently accessible to the various districts and ocean areas. The Administration Office, Navy Department, is the Navy's liaison with Federal Records Centers.

PERSONNEL TRAINING

The object of a training program is to increase the usefulness of an individual to the organization and to provide a climate and career incentives that will retain high caliber personnel. The many complex functions of controlling aircraft operations may be successfully accomplished only by integrated action of several individuals working together as a team. With these two facts in mind, it would be safe to say that training programs must provide for both individual and group training.

In this section it is intended to present some of the administrative aspects of the division training program; i.e., scheduling, recording accomplished training, and reporting to higher authority.

First, the ship or station will have a training program in effect as directed by higher authority. It normally consists of nonprofessional subject matter; that is to say, subject matter such as military duties and responsibilities or moral attributes not technically required within the AC rating. The Educaction and Training Officer, through the chain of command, will normally instruct the division training petty officer concerning subject material and required application to division personnel.

The training petty officer will normally establish and maintain the training program from the professional standpoint, for the division. The desired effect is to increase the individual's value to the division and retain high caliber personnel. Therefore, training must be directed toward qualifying air traffic controllers to maintain the desired level of controller personnel and to help individuals qualify and advance as rapidly as time requirements and their willingness and ability to accept more responsibility will allow.

10869

It is obvious that one man working alone cannot set up and execute an entire training program. The training PO, therefore, must select instructors from within the division to assist him. The ideal situation would be to have several qualified instructors in each watch section to maintain the formal instruction situation. However, the ideal never seems to exist. This places another large requirement upon the training PO. He must locate and train, if necessary, qualified instructors. This might be considered the most important link in the chain of events over which the training PO has control. If the instructors are not interested, motiviated, and well trained, chances are that the subject material will not reach the trainee because of one of various possible reasons. Therefore, the time spent in that particular training situation may be wasted, or if there is a complete lack of interest or necessity for the material concerned, the instructor may "gundeck" the local record with a net result of production of useless paperwork. This may not be apparent immediately, but it usually stands out when evaluated in terms of the following questions:

1. How many personnel made rates last time?
2. How smooth is the operation of the local facility when the weather is bad and traffic heavy?
3. What is the general attitude or morale of the division personnel?

Some of the problems the training PO must consider when compiling a training schedule are availability of people, an appropriate place where formal training can be accomplished, and the applicability to the various rates.

The schedule must be flexible since most ATC/OC personnel are watch standers with variable working hours. If at all possible, the training should be conducted during the watch when traffic will permit. There will be times, however, when watch standers will be required to attend training sessions even though they are off duty. The schedule should be simply stated and easy to follow. The general scheduled times for training will depend almost entirely upon the type of watch bill the division is working. The actual time of training is usually left to the discretion of the section leader within a specific time frame to allow optimum management practice.

Most facilities have a ready room available for formal training purpose use. If such a room is not readily available, then the training PO will have to make other arrangements for appropriate space. This may not seem very important; however, it has been proven over and over that the trainee will learn faster and retain more if the physical environment provides reasonable trainee comfort. If it is necessary to schedule and conduct training, then it should be necessary to consider every possible asset to effective presentation of the program.

The basis for applicability of each part of the training program to the various ratings should be the Record of Practical Factors, NavPers 1414/1 (AC). Few people realize the importance of practical factors to the individual. The basic decision factors for what will be taught in the service schools, what will be published in the Rate Training Manuals such as this one, and what will be covered by the fleetwide rating exams are covered in the Record of Practical Factors. If, then, the 1414/1 (AC) is thoroughly reviewed and used as a basis for determining the subjects to be taught in a formal training program, it would be logical that a trainee could receive considerable assistance in advancement and increase his value to the Navy by undergoing such training.

Keeping records of training is necessary as a reference for each individual concerned and for preparing reports of training accomplished. A training report for the division is accomplished in accordance with local directives, so that it blends into a department training report. A department training officer should be available for assistance with this report if needed. Various forms have been devised for recording training within a division; however, some use no form but merely handwritten reports. Figure 8-4 is an example of one facility's form for recording training within the section to submit to the training PO and reference for recording training received on an individual's training record. A record of training for each individual should be kept in the division files. One handy and personal way to accomplish this is to keep a folder for each man for record purposes and personal use. This individual training record should contain a record of practical factors, a record of all formal training received, and other local

qualifications such as designation of PAR IFR controller. Figure 8-5 is an example of an individual training folder and contents. This type recordkeeping allows the training PO to hand over the folder to the individual upon transfer so that he can show it to the new training PO at the next duty station and continue the process indefinitely.

Job Rotation

The practice of rotating men though the various phases of their rating is recognized as beneficial to the men and hence the Navy. A plan of rotation may be worked out covering several months by each section. The rotation schedule should show relief of mess cooks and compartment cleaners where necessary. This advance notice of such assignment and knowledge of what he will do when he returns to the division may help combat the feeling of many young men that they have been abandoned or eliminate the common belief that it is punishment for the individual concerned. By use of a rotation schedule the training PO can help the individual progress in knowledge and application of his acquired knowledge as he advances. Additionally, with periodic rotation, an individual is presented with challenges of new jobs and phases of the rating, and he is less likely to become disinterested and dissatisfied with his job and consequently the Navy.

Testing

The overall effectivness of a training program will be indicated by the proficiency with which trainees perform their various taks, by the demonstation of their understanding of the subject matter, and by the results returned from the rating exams. However, testing should not be overlooked as an important teaching tool and as a short term evaluation of the program progress.

The most difficult thing about testing is the job of compiling a test containing valid and thought-provoking questions. Since this job must be performed by the instructor, it may be one of the reasons that this method of teaching and evaluating is overlooked in many instances. A well-preparted test can generate lively discussion, instill a competitive spirit in the trainees, and provide them with a sense of accomplishment if they do well or an indication of areas where additional study is needed if they do poorly.

RESOURCES MANAGEMENT

Resources management systems are a series of systems designed to promote better management throughout the DOD by providing managers with improved means of obtaining and controlling resources required to accomplish missions.

Within the Department of the Navy, planning and programing are major functions of the Office of CNO and Headquarters, U.S.M.C. It is through the proper execution of these functions that the effort of the entire Navy Department is initially guided and subsequently controlled.

Navy programs are in general developed along a well ordered and clearly defined pattern. Requirements are identified, validated, and planned; plans are translated into programs; and programs are translated into budget requests which, upon approval, provide the dollars to produce the men, equipment, and facilities needed to satisfy requirements.

Budgeting is usually decentralized at large activities; that is, those composed of a number of departments. At such an activity, the commanding officer normally issues a budget call for the various activity components to develop their operating budget estimates and supporting data. In the budget call he communicates policy decisions, assumptions, and instructions based on guidance he has received through command channels, together with his projection of local program and workload objectives.

In preparing his budget, each department head translates the planning information into appropriate budget elements for each division or function under his management. He then assigns a realistic dollar estimate to each with the total representing his department's estimate. Completed departmental estimates are usually forwarded first to the activity comptroller for analysis and review by his staff. The comptroller then presents them to the commanding officer and offers such recommendations as he consid rs necessary. Senior AC's may be called upon to furnish a

RECORD OF PRACTICAL FACTORS
NAVPERS 1414/1 (AC) (8-67)

S/N-0106-801-9120

ACTIVE DUTY PERSONNEL

INSTRUCTIONS

1. As proficiency in each practical factor listed here is demonstrated, an entry is to be made in the DATE and INITIALS columns by the supervising officer.
2. All PFs must be demonstrated if equipment is available; if not, personnel may qualify by local written exams. In such cases make notations opposite those factors. For further information see Art. C-7201(2), BuPers Manual.
3. If a man demonstrates proficiency in skills considered to be within the scope of his rating but not listed in this list of minimum qualifications, an appropriate entry should be made on this form in the spaces provided unless the information is entered elsewhere in the man's service record.
4. A copy of this form is to be held by the division officer or by the appropriate supervising officer of each man in pay grade E-3 through E-8.
5. Upon transfer of an enlisted man, the supervising officer's copy of the form is to be signed, inserted in the correspondence side of the enlisted service record, and forwarded.
6. As changes in the rating structure and major changes in the Manual of Qualifications for Advancement in Rating, NAVPERS 18068B, occur, new forms will be made available. Minor changes in NAVPERS 18068B should be recorded in existing forms in the spaces provided.
7. One copy of the printed form should be made available to each man for his personal record and guidance.

USNR (INACTIVE DUTY) PERSONNEL

1. Reserve units will indicate the factors that cannot be completed at the Naval Reserve Training activity by a check (✓) in the USNR column. It is essential that the checked factors for the pay grade for which in training be completed on active duty for training. Additional factors requested for higher pay grades may be completed as time permits.
2. In "REMARKS" section on reverse of form, the ship, station, or unit providing training will enter explanatory notes concerning types of equipment used, extent, and frequency of training received, and similar data whenever appropriate.
3. Ship or station supervising officer must sign form for period of active duty for training.

10874

realistic estimate of division needs which the department will use in formulating the departmental estimate.

The operating budget prepared by the activity sets forth the annual plan of operations. It is the commanding officer's estimate of the total resources required throughout the year for performance of the activity's mission. The budget as approved by proper authority sets forth the actual resources available, and it is against these amounts that performance and expenditures are evaluated.

Operating target amounts will be approved by the commanding officer and allocated to individual departments. These amounts should not be exceeded by the target holders unless proper authorization has been made by the commanding officer.

Fund authorizations are administratively controlled through the issuance of job orders. All labor and materials charges are identified by job order. The job order is the means by which expenditures are accumulated for cost analysis and for charge to the proper appropriation. Current accounting directives require that the cost of military labor be included in the budget estimates and execution.

Budget holders are required to make a monthly report of military services. Therefore, some method of timekeeping must be implemented locally to allow accumulation of the figures necessary for the report. One such method used frequently is the exception method; that is, only the exception to normal is reported. The basic premise for such a system is that a predetermined normal job order number is assinged to military labor, timekeeping is accomplished daily, and a weekly report of exception data is made.

Each department should designate timekeepers and coordinators as necessary for accurate daily recording. The coordinator would be the division level petty officer assigned this task. The normal would be a 40-hour week. The coordinator would record absences of 1 hour or more, including TAD, leave etc., and report them as an exception. Then the department could, with the current hourly rate of pay, compute the cost of military services, compare the actual cost against the approved budget, and use current data for future estimates.

Collateral Equipment Requirements

Collateral equipment in this section refers to furniture, furnishings, appliances, and equipment which an ATC division makes use of in the assigned working spaces. Senior AC's must necessarily concern themselves with the required amount and condition of collateral equipment used by their division. Availability and good condition of proper furniture and equipment are factors contributing to proper attitude and morale of junior personnel.

As stated previously, funds are requested based on future needs and requirements. Each station has local instructions which outline procedures for submitting requirements for collateral equipment. This is accomplished at the department level to the station comptroller at various times during the fiscal year. Senior AC's are in a position to recognize the need for future requirements and replacement of aging equipment. These needs must be made known to the division officer for coordination with the department head so that the requirements can be included in the latters report of equipment requirements. Again, conditions change due to the period of time between request and receipt of funds; hence requirements may not always be filled as planned. These requirements are not automatically carried over into the next reporting period but must be restated.

The comptroller's office maintains records on all accountable equipment aboard an air station. At certain intervals, inventories are conducted to keep the records of the equipment current. If equipment is broken or lost, the department head and division officer in whose spaces the equipment was located must initiate survey action to determine cause and recommend requisitioning action required by the results.

Requisitioning

The Navy has already purchased most of the material and supplies needed by activities. The procedure for requisitioning supplies may vary between stations. Most large air stations have a storekeeper assigned to the operations department or one individual trained by the supply department for the actual completing of the standard requisition, DD form 1348. A relatively

10873

10874

but would see the target return. Chaff jamming is easily countered by the incorporation of circuits which reject abnormally slow moving targets such as chaff, corner reflectors, balloon borne devices, and etc.

To further increase the difficulty in jamming the pulse compression type of radar, the PRF could be made to vary at random rate. This will cause each and every frequency in the transmitted pulse to change slightly each time the transmitter fires. Unless the returning echo contains exactly the same frequencies that were just transmitted, the matched filter will reject them.

10851

new concept of providing office and general supplies is the SERVMART system. These SERVMART's resemble a private self-service store. The petty officer responsible for maintaining supplies determines what is needed, obtains the approval from the officer within the department authorized to approve such expenditures by obtaining a signed DD form 1348 for an amount not to exceed the total cost of the supplies needed. The supplies may then be picked up at the SERVMART and the actual amount of purchase recorded on the DD form 1348. The various copies of the form are distributed to the necessary individuals so that the amount of the purhcase can be charged against the funds allocated to the department and the station.

Of course every need cannot be satisified by the SERVMART system. When the requirement exists, a properly completed DD form 1348 must be submitted through the supply department so that they can order what is required. In order to procure exactly what is needed when requisitioning supplies, the correct Federal stock number is required.

Plant Property Accounting

Plant property is all Navy-owned and Navy-controlled real and personal property of a capital nature located in the Naval Shore Establishment.

Plant property is divided into four classes: Class 1 (land); Class 2 (buildings and improvements); Class 3 (equipment, other than industrial plant equipment); and Class 4 (industrial plant equipment). It is around these classes of property that the inventory control system for plant property is built.

The inventory control system for plant property is designed to provide controls essential for compliance with statutory and DOD requirements concerning Government property. It provides for Navy-wide collecting, compling, recording, and reporting of plant property information. The system meets the objective of furnishing factual information on capital equipment to both financial and technical management. By requiring a reconciliation with funds expended for plant property, the system also insures that all such property in the Navy is accounted for.

The fiscal officer at each activity is charged with the establishment and maintenance of plant property account records. He must institute local procedures to insure compliance with directives and instructions issued by higher authority.

Department heads at each activity are responsible for plant property under their custody. In addition they must assist the fiscal officer in obtaining technical descriptions of plant property; affixing identification plates and decals on the property; determining the estimated life of property; reporting acquisitions, dispositions, transfers, and surveys of plant property; and conducting physical inventories.

FORMS, RECORDS, AND REPORTS

The Navy Stock List of Forms and Publications, NavSup 2002, contains a complete numerical listing of all available naval forms and publications distributed by the Navy and stocked for issue.

NOTE: There are a few exceptions to the above statement such as Aeronautical Charts and Publications discussed earlier in this manual.

Section I of the stock list is a general introduction in the use of the publication. Instructions for the breakdown of the columnar headings as they appear in the stock list, requisitioning instructions, etc., which if carefully studied should help determine the correct procedure for ordering the necessary forms and publications required for administrative functions.

The remaining sections of the stock list contain forms and publications which have been categorized on the basis of departmental sponsorship and/or functional usage. For example, section II contains forms used by the Navy. In section II can be found the NavPers Form 1414/1, AC Record of Practical Factors, and OpNav Forms 3722/1 and /2 used when submitting OpNav Report 3722-1. Section III contains BuPers publications. In section III can be found the AC 3 & 2 and 1 & C training manuals. Section VIII, parts C & D, contains aeronautical manual and letter publications such as technical

manuals for specific radar equipment. AC's may be interested in the operator's section of these manuals.

Aviators Flight Logbook

The Aviators Flight Logbook currently in use is OpNav Form 3760-31. This book is bound with a navy blue cover. Each naval aviator, naval aviation pilot, naval student pilot, and naval flight officer possesses a currently maintained aviators Flight Logbook. Possession of such a logbook by other personnel on duty involving flying is neither required nor prohibited. Each duly issued Aviators Flight Logbooks is considered to be the personal property of the individual who is currently, or in the past was, required to possess it.

AC's aboard ship assigned to the Air Operations branch of the OC division may be required to assist the ship's pilots in keeping their logbooks current. Instructions for coding the flight to indicate classification of flights are included in the front part of each logbook. Additional information may be found in the current OpNav Instruction 3710.7.

Manpower Authorizations

Manpower Authorizations reflect two expressions of naval manpower defined as follows:

1. Complement.

a. Fleet Units. The quantitative and qualitative naval personnel needs of an activity to effectively carry out all missions and tasks in wartime. This includes the ability to perform all equipment maintenance and to maintain Readiness Condition III and full power operations for indefinite periods as well as providing 100 percent battle station manning.

b. Shore Activities. The quantitative and qualitative naval personnel needs of an activity to effectively perform all tasks envisioned when moblized.

2. Allowance.

a. Fleet units. The quantitative and qualitative naval personnel needs of an activity to effectively carry out all missions and tasks in peacetime. This includes the ability to perform all equipment maintenance, carry out normal operating and training, and maintain Readiness Condition III and full power operations for limited periods, varying by type from 72 hours to 1 week, after which capacity for sustained effort is progressively reduced.

b. Shore Activities. The quantitative and qualitative naval personnel needs of an activity to effectively perform all peacetime operations.

While the CNO has responsibility for the preparation of Manpower Authorizations, commanding officers can assist in insuring the accuracy of their Manpower Authorizations by reviewing and submitting justified requests for changes. In reviewing Manpower Authorizations, it is of the utmost importance that the need for increases or reductions in both allowances and complements be considered and insure that the skills reflected in the Manpower Authorizations are valid.

Requests for changes to Manpower Authorizations may be submitted under the following circumstances:

1. Quantitive increases in allowances which are required to accommodate valid requirements resulting from changes in missions, tasks, or equipments.
2. Quantitative and/or qualitative reductions in allowances when the needs of an activity can be met with personnel in fewer numbers or lesser grades or rates than those authorized.
3. Qualitative changes in allowances when deemed necessary.
4. Quantitative and/or qualitative changes in complements when deemed necessary.

Manpower Authorization format, OpNav 1000/2, is normally held in the activity Personnel Office. Senior AC's should periodically review that portion applicable to the ATC division for possibly better utilization of manpower and when necessary initiate action for changes to the Manpower Authorizations.

Figure 8-6 is an example of a facility's OpNav Form 1000/2. To be absolutely sure that this is the very latest information, access must be available to all changes approved for the basic document since it was printed or reprinted.

From studying the form in figure 8-6, it can be seen that the operations leading chief billet at this particular activity is an E-8

billet and that the ATC division leading chief billet is an E-9 billet. This is an apparent discrepancy in that the ATC division is a part of the operations department. This situation could be resolved by changing the operations leading chief billet to an E-9 billet. However, suppose that all concerned decided that the duties performed by the ATC leading chief were such that the billet should properly be an E-8 billet. In such instances a change request on the proper form as shown in figure 8-7 is submitted as an enclosure to a cover letter containing justification for the change.

Change requests for Manpower Authorizations are submitted on OpNav Form 1000/3. (See fig. 8-7.) Complete instructions and information on Manpower Authorizations can be found in OpNav Instruction 1000.16 (Series). A revised Manpower Authorization is not promulgated each time a change is made. Significant changes will usually result in a complete reprinting, while minor changes do not justify the cost of reprinting and distribution.

A later section of this chapter, headed "Navy Correspondence," contains a sample of a letter that would accompany the 1000/3 form shown in figure 8-7.

The current information in the manpower system can be determined by checking the latest BuPers Report 1080-14 for enlisted personnel.

Enlisted Distribution and Verification Report

The Enlisted Distribution and Verification Report, BuPers Report 1080-14, is a report common to the activity and the distributional authority. It is a basic decision document which is used by the distributor to determine the activity's enlisted personnel status and requirements. The report is normally held in the activity personnel office. Senior AC's should review this monthly report periodically to insure that all the information contained in the report is correct. If an error is found, it should be brought to the attention of personnel so that they can initiate change action. The report is a machine printed report that contains a considerable amount of information about individuals in the division. For a breakdown on the code system used in the report, refer to chapter 6 of the Naval Manpower Information System Manual, NavPers 15642.

Figure 8-8 is an example of BuPers Report 1080-14, showing a partial listing of Air Controlmen at an air station.

Air Controlman Data Card

Personnel serving in BuPers-controlled billets in air traffic control facilities and all Air Controlmen must submit an Air Controlman Data Carda (NavPers 1306/6) directly to the Chief of Naval Personnel (Pers B2144). The submission cycle is 6 to 8 months prior to an individual's tour completion date (TDC). Additional cards may be submitted as changes occur.

Data cards are used by the Chief of Naval personnel for the efficient and orderly rotation of Air Controlmen. They are most important to the individual in that they are the ONLY information furnished the Air Controlman detail officer concerning the individual's duty choices and other pertinent assignment data.

Figure 8-9 is an example of AC data card, front and back.

The data card should be filled out by the individual concerned. Senior AC's must assist their men since they may be unfamiliar with the various schools available or may want information about a particular duty station to determine their choices. Also some of the newer individuals may not even be aware of the data card or the system of submission.

On the back of these cards is space for the division officer's evaluation of the individual's qualifications in air traffic control duties performed and space for recommendation of E-6 and above for instructor duty or to a strictly administrative billet filled by an AC. This helps the detail officer select the best qualified men for those important billets.

Air Traffic Activity Report

Commanding officers of shore activities operating ATC facilities are required to submit an Air Traffic Activity Report semiannually as of 30 June and 31 December. This report is assigned the report symbol 3721-13. The report is accomplished by completing OpNav

10885

10881

Form 3721/12 shown in figure 8-10. Air traffic activity at satellite airfields (OLF and ALF) is reported by the parent activity.

Various uses of the information required by this report, such as budgetary, statistical, or trend information, are made by both CNO and FAA. Therefore a copy of the report is sent to FAA. Each facility must keep records of aircraft operations religiously to insure accurate data for the report. The instructions for completing OpNav Form 3721/12 are included on the back of the form. The instructions include the following definitions of terms for the purpose of this report and standardization of recordkeeping:

1. Aircraft Operations. Count aircraft operations as follows:

a. Count an arrival or departure as one operation.

b. Count aircraft touch and go landings as two operations.

c. Count an approach followed by a waveoff as two operations; e.g., field carrier landing practice or practice instrument approaches to minimium descent altitude or decision height.

d. Count each aircraft which transits the control area of jurisdiction and is provided ATC services as one operation.

e. Count aircraft operating in a formation as a single aircraft except when the formation breaks up into smaller formations or single aircraft. When this occurs, count each additional formation or single aircraft as a separate aircraft operation.

2. Instrument flight rules operations. An IFR operation is the handling by an ATC facility of the arrival or departure of an aircraft operating in accordance with instrument flight rules or the provision of IFR separation from other aircraft. Instrument operations must be counted whenever aircraft are provided IFR separation regardless of the existing weather conditions or the type of flight plans.

3. Visual flight rules operations. A VFR operation is an aircraft operation conducted in accordance with visual rules, except when the aircraft is being provided IFR separation from other aircraft.

4. Radar approaches. Any surveillance or precision radar approach to a landing, missed approach, or waveoff. Each approach executed must be counted, regardless of the flight rules under which the aircraft is operating or the existing weather conditions.

5. Automatic carrier landing system approaches. Activities with ACLS capability must report approaches and the mode of approach utilized in the appropriate spaces on the form.

NAALS Program

Naval Air Traffic Control, Air Navigation Aids and Landing Systems (NAALS) program is the subject of OpNav Instruction 3721.5 (Series). The purpose of the instruction, and hence of the program, is to promulgate policy and guidance for planning, programming and implementation of ATC, navaid, and landing system equipment at Navy and Marine Corps aviation activities ashore and afloat.

It is necessary for operating commands to continually review their NAALS operational capability to identify needed improvements. The need for an improved operational capability at an activity may be identified by any command responsible for supporting aircraft operations, by the Chief of Naval Material (CNM), by CNO, or may be imposed by FAA regulations. The need may stem from a technical deficiency in the installed equipment or from an operational deficiency that limits or derogates the operational capability of the ATC facility to support the mission and tasks assigned the aviation activity. The relief of these deficiencies may require additional or substitute equipment or the development of new equipment. Further, a need for an improved capability may arise from prospective rulemaking by the FAA which requires advanced planning at the Navy Department level.

Two formats are established as enclosures to OpNav Instruction 3721.5 (Series), titled NAALS Operational Capability Improvement Request (OCIR) and Master Implementation Plan (MIP). The OCIR, which is a typewritten format, delineates the deficiency, required operational capability, solution, and relative priority, in that order, that is submitted as a request for improved operational capability. The MIP is the responsibility of CNM which shows the operational requirements and programed equipments for the entire Navy and is revised semiannually for use by CNO. OCIR's having sufficient justification and not involving research and development may be reflected as revisions to the MIP, thereby becoming part

CHAPTER 16

RADAR CIRCUITS

The purpose of this chapter is to review the principles which determine the characteristics of radar circuits and to follow this review with a discussion of how these circuits are applied in a typical radar set.

Among the principles which should be reviewed before continuing with the present discussion are certain factors which affect radar performance. Such factors are carrier frequency, pulse width and PRF, power relation (relation between peak and average power), beam width, and scan rate. The choice of these arbitrary constants for a particular system is determined by its tactical use, the accuracy required, the range to be covered, the practical physical size, and the problem of generating and receiving the signal. Basic information concerning these factors may be found in Basic Electronics. Other factors, such as antenna characteristics, wave guide design, and special circuits, have already been discussed in previous chapters of this course.

Three categories of basic circuits are discussed in the following paragraphs. These are timing circuits, sweep circuits, and transmitter circuits.

TIMING CIRCUITS

Timing or control is the function of the majority of the circuits in radar. Circuits in a radar set accomplish this function by producing a variety of voltage waveforms, such as square waves, sawtooth waves, trapezoidal waves, rectangular waves, brief rectangular pulses, and sharp peaks.

In sound and in radio, tubes operate within the limits for which they are designed; but in radar timing circuits, they are often violently overdriven, frequently operating at points which range from well in the grid current region to far beyond cutoff. Although all of these circuits are broadly classified as timing circuits, the specific function of any individual circuit might be timing, waveshaping, or wave generating.

The basic function of the radar timer is to synchronize the sweep voltage or current for the indicator with the transmitter pulse. The specific function is to produce the trigger pulse that starts the transmitter, the sweep circuits, rangemark generators, blanking circuits, and gating circuits. (See figure 16-1.)

BASIC REQUIREMENTS

The basic timing circuit should meet three basic requirements:

1. It must be free running (astable)—since the timer is the heart of the radar, it must establish the zero time reference and the PRF.
2. It must be stable in frequency (PRF)—the PRF, or its reciprocal, the PRT, must not change between pulses for accurate ranging.
3. The frequency must be variable in steps—for the radar to operate on different ranges.

There are three basic circuits that can meet the above mentioned requirements. They are the sine-wave oscillator, single-swing blocking oscillator, and the master trigger multivibrator.

The multivibrator timer is discussed because of its greater usage due to its better frequency stability.

MULTIVIBRATOR TIMER

Some of the information dealing with multivibrators, as presented in this chapter, may seem repetitious of Basic Electronics. Since this chapter is written for Aviation Electronics Technicians First and Chief, the treatment of multivibrators must be more thorough. The preliminary data is given as an aid in introducing more complicated aspects of the subject.

The multivibrator (square wave generator) is a form of relaxation oscillator. There are several different types in use, depending on the function they are required to perform. They are used for time sharing, gating, counting, and timing bases. Some of these circuits produce a

of the implementation cycle. This determination is made by CNO; however, in many instances that office depends upon feeder information from the aviation activities—hence the personnel who man and operate them.

Commanding officers of aviation activities ashore and afloat must review the NAALS operational capability of their respective activities on a continuing basis. Whenever a NAALS deficiency is identified pursuant to this review, a NAALS OCIR is completed and submitted to CNO (OP-53).

Frequency Usage Report

The radiofrequency spectrum has become increasingly congested as a result of the development of electromagnetic equipment and an increasing international requirement for radiofrequencies.

Frequency utilization data is a most valuable evidence to justify retention and to manage existing frequency resources. The Military Communications-Electronics Board, Joint Chiefs of Staff, has directed that frequency usage information be provided by the military services for inclusion in a Joint Radio Frequency Management Program.

U.S. Navy and Marine Corps acitivities and ships utilizing radiofrequencies for communications purposes must prepare a Frequency Usage Report, OpNav Report 2400-1.

The Communications Department normally prepares this report. However, senior AC's are frequently called upon to assist in its preparation by providing an accurate estimate of frequency usage for air traffic control at the facility. Complete information on this report is found in OpNav Instruction 2400.7 (Series) and JANAP 195, plus information on how to get new frequencies or delete old ones when required. This report is classified Confidential.

Figure 8-11 is an example of a Frequency Usage Report.

NAVY CORRESPONDENCE

The Navy Correspondence Manual prescribes policies and outlines procedures for the preparation of correspondence in the Department of the Navy. These policies and procedures are followed unless prescribed otherwise by the Secretary of the Navy or by his authority.

The selection of the proper communication for use in transmitting information is of special importance in Navy operations. Listed below are some of the types of correspondence and their uses:

1. Naval Letter. The naval letter is used by all activities of the Department of the Navy as a formal means of intranaval communication. It may be used also in addressing other agencies, either governmental or nongovernmental, which are familiar with the style. (See fig. 8-12.)

2. Joint Letter. When officials of two or more activities need to issue a letter concerning a particular subject of common interest to the activities, a joint letter is prepared. It may be directed to one addressee, or to two or more addresses identified separately or as a group. (See fig. 8-13).

3. Speedletter. A speedletter is a form of naval correspondence used for urgent communication which does not require electrical transmission. It is not used for directives. The primary purpose of the speedletter is to call attention to the communication, so that it will be handled as promptly as possible by the recipient. (See fig. 8-14.)

4. Memorandum. A memorandum is a form of naval correspondence used for informal communications within and between headquarters components of the Navy Department, between fleet and force commanders and units of command under their justification, and within a field activity. It may be directed to one or more addressees.

The naval letter is perhaps the most formal type of correspondence used by the Navy, but this does not mean that its content cannot be simple. Avoid long sentences and long words where short sentences and short words convey the same meaning. Each paragraph should contain one complete thought expressed in logical sequence. Tables, diagrams, and sketches should be included as enclosures if necessary to add to the clarity of the letter.

Figure 8-15 is an example of a smooth naval letter associated with the change request for a local Manpower Authorization format.

APPENDIX I

DEFINITIONS AND ABBREVIATIONS

AL.—Approach and Landing (Chart).

APPROACH SEQUENCE.—The order in which aircraft are positioned while awaiting approach clearance or while on approach.

CONTROLLING OBSTRUCTION.—The highest obstruction relative to a prescribed geometric plane within a specific area.

DECISION HEIGHT (DH).—The height, specified in MSL, above the highest runway elevation in the touchdown zone at which a missed approach must be initiated if the required visual reference has not been established. This term is used only in procedures where an electronic glide slope provides the reference for descent, as in ILS or PAR.

FAC.—Final approach course.

FAF.—Final approach fix.

FLIGHT INSPECTION.—In-flight investigation and certification of certain operational performance characteristics of electronic and visual navigation facilities by an authorized inspector in conformance with the U.S. Standard Flight Inspection Manual, NavAir 16-1-520.

GPI.—Ground point of intercept. A point on the runway centerline at which it is assumed that a straight line extension of the glide slope intercepts the runway surface.

HAA.—Height above airport. Indicates the height of the MDA above the published airport elevation. This is published in conjunction with circling minimums. (Civilian only.)

HAT.—Height above touchdown. Indicates the height of the DH or MDA above the highest evelation in the touchdown zone. This is published in conjunction with straight-in minimums. (Civilian only.)

IAC.—Initial approach course.

IAF.—Initial approach fix.

IC.—Intermediate course.

IF.—Intermediate fix.

JAL.—High altitude approach and landing(Chart).

MAP.—Missed approach point. A point specified in the approach procedure which may be the point of intersection of an electronic glidepath with a decision height or MDA, a navigation facility, a fix, or a specified distance from the final approach fix, at which a pilot on approach will commence missed approach procedure if visual requirements for a landing do not exist.

MDA.—Minimum descent altitude. The lowest altitude to which descent can be authorized in procedures not using a glide slope. Aircraft are not authorized to descent below the MDA until the runway environment is in sight, and the aircraft is in a position to descend for a normal landing.

MHA.—Minimum holding altitude.

OBSTRUCTION.—An existing object, object of natural growth, or terrain at a fixed geographical location, with reference to which vertical clearance is or must be provided during flight operation.

OBSTRUCTION CLEARANCE.—The vertical distance between the lowest authorized flight altitude and a prescribed plane within a specific area.

PENETRATION.—That portion of a published high altitude instrument approach procedure which prescribes a descent path from the fix on which the procedure is based to a fix or altitude from which an approach to the airport is made.

PLATFORM.—A point 5,000 feet in the approach pattern at which all jet and turboprop aircraft will decrease their rate of descent to not more than 2,000 feet per minute, continuing letdown to the 10-mile gate. (Carriers only.)

PRECIPITOUS TERRAIN.—Terrain characterized by steep or abrupt slopes.

RUNWAY ENVIRONMENT.—The runway threshold or approved lighting aids or other markings identifiable with the runway.

10880

10890

SEGMENT.—The basic functional division on an instrument approach procedure. The segment is oriented with respect to the course to be flown; i.e., intermediate, initial, or final approach segment.

TRANSITIONAL LEVEL.—The flight level below which heights are expressed in feet MSL and are based on approved station altimeter settings.

TDZ.—Touchdown zone. The first 3,000 feet of runway beginning at the runway threshold.

TDZ ELEVATION.—The highest elevation in the TDZ.

TERMINAL AREA FACILITY.—A facility providing air traffic control service for arriving and departing IFR aircraft and, on occasion, tower en route control service.

TOWER EN ROUTE CONTROL SERVICE.—Departure, en route, and arrival control service provided to IFR aircraft by one or more terminal area facilities.

Figure 16-1.—Synchrogram of timer pulses.

specified wave shape repeatedly as long as power is supplied. Others produce one wave when pulsed, and remain inactive until another pulse is applied to the circuit; then they produce another wave. The output wave shape is the same regardless of the waveshape or amplitude of the initiating or TRIGGER pulse. Those which run continuously with only power applied are called free-running multivibrators. Those which produce one complete cycle of operation for each synchronizing pulse are called ONE-SHOT, ONE-CYCLE, or MONOSTABLE. Those which produce only a half cycle of operation for each synchronizing pulse are called BISTABLE, FLIP-FLOP, or SCALE-OF-TWO circuits. The frequency of free-running multivibrators, as with other types of oscillators, is influenced by all voltages and component sizes associated with the circuits. Therefore, although such circuits have only fair frequency stability when free running, adequate stability is readily achieved from a reliable a-c synchronizing voltage.

The square waveshape produced can be differentiated to produce accurately spaced peaked waveshapes. The duration and amplitude of any of the waveshapes are readily varied. Time delayed pulses can be produced by triggering a multivibrator with a peaked wave, letting it go through a cycle, and obtaining a new peaked wave somewhat later from the square wave produced.

Plate Coupled Multivibrator

The plate coupled multivibrator is the simplest of the multivibrators. The basic operating principles of this circuit are discussed in Basic Electronics. The following paragraphs are devoted to a quantitative analysis of the circuit and a discussion of methods for improving circuit action.

QUANTITATIVE ANALYSIS.—It is fairly easy to calculate the frequency and approximate voltage throughout a given circuit of this type. Consider, for example, the circuit shown in figure 16-2 (A). A plate voltage of 300 volts is applied to a 6SN7 dual triode with the circuit components shown. The plate voltage of V1 varies between the value corresponding to zero grid voltage and the value corresponding to zero plate current. You can determine these values from a 20-K loadline on the 6SN7 characteristic curves. The loadline crosses the zero grid voltage line at a plate voltage of 97 volts. At zero plate current, the plate voltage is 300 volts. From this information you can construct the plate voltage waveshape.

MF AVAILABLE IN VT-ERIC SET.
NAVPERS 10358-D
Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402 (D208.11:A17/16/970, $3.25).
PUB DATE - 70 384p.

DESCRIPTORS - *MANUALS; VOCATIONAL EDUCATION; *INSTRUCTIONAL MATERIALS; MILITARY PERSONNEL; *MILITARY TRAINING; RESOURCE MATERIALS; *AVIATION TECHNOLOGY; TECHNICAL EDUCATION; *TRADE AND INDUSTRIAL EDUCATION; ADVANCED PLACEMENT PROGRAMS; FLIGHT TRAINING; JOB TRAINING

ABSTRACT - Prepared by the Navy Training Publications Center, this manual is to be used by enlisted Naval personnel studying for advancements in the Aircrew Survival Equipmentman (PR) rating. Arranged in 20 chapters, this information includes sections on: (1) Parachute Familiarization, (2) Automatic Parachute Actuators, (3) Fasteners, (4) Standard Liferafts and Equipment, (5) Oxygen, and (6) NES-8A and NES-8B Personnel Parachute Assembly. Numerous illustrations, a reading list, and an index are included. (JS)

AIRCREW

SURVIVAL EQUIPMENTMAN 3 & 2

BUREAU OF NAVAL PERSONNEL
RATE TRAINING MANUAL NAVPERS 10358-D

PREFACE

This Rate Training Manual was prepared for enlisted personnel of the Regular Navy and the Naval Reserve who are studying for advancement in the Aircrew Survival Equipmentman (PR) rating. It is based on the professional qualifications for advancement to PR3 and PR2, as set forth in the Manual of Qualifications for Advancement, NavPers 18068 (Series).

The manuscript for this training manual was prepared by the Navy Training Publications Center, Millington, Tennessee, for the Bureau of Naval Personnel. Technical reviews were provided by personnel of the Aircrew Survival Equipmentman Schools, Lakehurst, New Jersey; the Naval Examining Center, Great Lakes, Illinois; and the Naval Air Systems Command, Washington, D.C.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

READING LIST

United States Armed Forces Institute (USAFI) courses for additional reading and study are available through your Educational Services Officer.* The following courses are recommended:

E 275 General Science I

E 290 Physics I

*"Members of the United States Armed Forces Reserve components, when on active duty, are eligible to enroll for USAFI courses, services, and materials if the orders calling them to active duty specify a period of 120 days or more, or if they have been on active duty for a period of 120 days or more, regardless of the time specified on the active duty orders."

CHAPTER 1

AIRCREW SURVIVAL EQUIPMENTMAN (PR) RATING

Many men engaged in a great number of specialized fields are needed to maintain the Navy's air arm in a condition of constant military readiness. All of these specialists are mutually dependent, and each contributes his part to the efficient operation of the entire organization. An important member of this team of specialists, which keeps naval aviation the most potent force of its kind in the world, is the PR.

The PR has as his primary mission the business of saving lives, a mission equally important in peace and in war. One generally thinks of the aviator as trusting his life to the aircraft he is flying. However, if for some reason the aircraft becomes disabled, the aviator's probability of survival would be small—except for the equipment that the PR has provided for such an emergency. With this equipment, aviators and their crews are able to abandon their disabled aircraft, parachute to safety, and survive on land, at sea, or even in the arctic wastelands.

This training manual is designed to help you meet the professional qualifications for advancement to Aircrew Survival Equipmentman Third and Second Class. The Aircrew Survival Equipmentman qualifications which are used as a guide in the preparation of this manual are current through the latest revision of the Manual of Qualifications for Advancement, NavPers 18068 (Series).

Chapter 1 gives information on the enlisted rating structure, the PR rating requirements, and procedures for advancement. It also includes references that will help you in working for advancement and in performing your duties.

Chapter 2 covers the Naval Aircraft Maintenance Program and Aircraft Maintenance Forms and Records involved in the implementation and maintenance of this program.

Chapter 3 is titled "Parachute Familiarization" and covers introduction to parachutes, types of parachutes, and components of parachutes.

Chapter 4 is concerned with parachute inspection and the arrangement of a parachute loft and facilities. It covers the purpose of parachute inspection, factors affecting malfunctions, inspection intervals, inspection procedures, and the general floor plan of a typical parachute loft.

Chapter 5 discusses parachute packing and rigging. It covers the rigging tools, packing tools, removing suspension line entanglements, handling packed parachutes, and safety precautions.

Chapters 6 and 7 present information on packing and rigging the NC-3 and NB-11 parachutes with and without the pararaft.

Chapter 8 deals with the Martin-Baker parachutes and the Martin-Baker drogue parachute.

Chapter 9 discusses the Master Specialties 1000 series automatic parachute actuator. It covers information on preparation, maintenance, inspection, and safety precautions.

Chapter 10 deals with parachute maintenance and repairs. It gives information on fabric materials, tapes and webbing, precautions against fabric damage, parachute cleaning, stenciling, and types of stitches and seams.

Chapter 11 is devoted to sewing machine familiarization, cleaning, and lubrication.

Chapter 12 covers the different types of fasteners, such as snap fasteners, grommets, speedy rivets, hook and pile tape, and slide fasteners.

Chapter 13 is titled "Protective Helmets and Oxygen Masks," and covers the various types of helmets and oxygen masks used by the Navy.

Chapter 14 lists some of the different types of flight clothing and protective equipment, such as flight suits, torso harness suit, anti-g suit, antiexposure suits, and flight boots.

10903 10902

Chapter 15 is titled "Standard Liferafts and Equipment," and covers multiplace liferafts and single place liferafts.

Chapter 16 deals with recharging carbon dioxide cylinders. It covers CO_2 recharge equipment and liferaft inflation requirements.

Chapter 17 discusses safety belts, shoulder harnesses (V and H types), and the testing machine.

Chapter 18 is devoted to oxygen. It deals with test stands, regulators, and controllers.

Chapter 19 introduces the NES-8A personnel parachute assembly. It discusses the operation and packing procedures for this unit.

Chapter 20 presents the NES-8B parachute. It is devoted to the sequence of events of operation and packing procedures.

ENLISTED RATING STRUCTURE

The present enlisted rating structure consists of general ratings and service ratings.

General ratings identify broad occupational fields of related duties and functions. Some general ratings include service ratings; others do not. Both Regular Navy and Naval Reserve personnel may hold general ratings.

Service ratings identify subdivisions or specialties within a general rating. Although service ratings can exist at any petty officer level, they are most common at the PO3 and PO2 levels. Both Regular Navy and Naval Reserve personnel may hold service ratings.

PR RATING

The PR rating is a general rating and is included in Navy Occupational Group IX (Aviation). There are no PR service ratings.

Figure 1-1 illustrates the path of advancement from Recruit to Master Chief, Warrant Officer, or Limited Duty Officer. Figure 1-1 indicate career stages from which qualified enlisted men may advance to Warrant Officer (W-1) and selected Commissioned Warrant Officers (W-2 and W-3) may advance to Limited Duty Officer.

The Aircrew Survival Equipmentman (Class A) School, located at Lakehurst, New Jersey, is designed to provide PR strikers with the understanding and knowledge which lead to the fulfillment of the technical requirements for advancement to PR, Third Class. The

PR.1

Figure 1-1.—Path of advancement.

opportunity is provided to make one premeditated free-fall descent, using a parachute packed by the student, under the supervision of a qualified instructor. This is on a strictly voluntary basis after the man arrives at the school.

Entrance requirements to the school are as follows:

Candidate must have a minimum GCT plus MECH score totaling 105. Twenty-four months

of obligated service from the date of entry is required.

The Third Class and Second Class PR's have the following duties to perform:

Inspect, maintain, and repair parachutes, survival equipment, and flight and protective clothing and equipment. Pack and rig parachutes. Pack and equip rafts. Repair and test oxygen regulators, controllers, oxygen bailout bottles, and liquid oxygen converters removed from aircraft. Fit and maintain oxygen masks, flight clothing, antiexposure suits, and anti-g suits. Operate and maintain carbon dioxide and oxygen shop transfer and recharge equipment. Operate oxygen component test stands. Operate and make minor adjustments on sewing machines. Test safety belts and shoulder harnesses removed from aircraft. Assist in supervising the operation of parachute lofts, oxygen shops, and survival shops, and instruct personnel in the proper techniques of survival.

LEADERSHIP

As you advance to PR3 or PR2, more and more of your worth to the Navy is judged on the basis of the amount of efficient work you are able to obtain from the men under your supervision. The Secretary of the Navy has outlined some of the most important aspects of naval leadership in General Order Number 21.

Naval Leadership is the art of accomplishing the Navy's mission through people. It is the sum of those qualities of intellect, of human understanding, and of moral character that enables a man to inspire and to manage a group of people successfully. Effective leadership, therefore, is based on personal example, good management practices, and moral responsibility.

The Naval Leadership Program is a continuing program to develop those qualities of leadership, to the greatest extent possible, in all people within the Naval Establishment.

ADVANCEMENT

Some of the rewards of advancement are easy to see. You get more pay. Your job assignments become more interesting and more challenging. You are regarded with greater respect by officers and enlisted personnel. You enjoy the satisfaction of getting ahead in your chosen Navy career.

The advantages of advancement are not yours alone. The Navy also profits. Highly trained personnel are essential to the functioning of the Navy. By advancement, you increase your value to the Navy in two ways: First, you become more valuable as a person who can train others and thus make far-reaching contributions to the entire Navy; and second, you become more valuable as a technical specialist in your own rating.

HOW TO QUALIFY FOR ADVANCEMENT

What must you do to qualify for advancement? The requirements may change from time to time, but usually you must:

1. Have a certain amount of time in your present grade.
2. Complete the required Rate Training Manuals by either demonstrating a knowledge of the material in the manual by passing a locally prepared and administered test, or by passing the Enlisted Correspondence Course based on the Rate Training Manual.
3. Demonstrate your ability to perform all the practical requirements for advancement by completing the Record of Practical Factors, NavPers 1414/1.
4. Be recommended by your commanding officer, after the petty officers and officers supervising your work have indicated that they consider you capable of performing the duties of the next higher rate.
5. Successfully complete the applicable military leadership examination which is required prior to participating in the advancement (professional) examination.

Some of these general requirements may be modified in certain ways. Figure 1-2 gives a more detailed view of the requirements for advancement of active duty personnel; figure 1-3 gives this information for inactive duty personnel.

Remember that the requirements for advancement can change. Check with your educational services office to be sure that you know the most recent requirements.

Advancement is not automatic. After you have met all the requirements, you are eligible for advancement. You will actually be advanced only if you meet all the requirements (including making a high enough score on the written examination) and if quotas permit.

10904

Figure 16-2.—Quantitative analysis of plate coupled multivibrator.

All this plate voltage change occurs across the grid resistor of V2 at the first instant. The resistor voltage is the grid voltage for V2; so the grid will swing negative by the same amount that the plate voltage drops. The plate voltage drops from 300 to 97, or 203 volts. The grid is at zero when the plate voltage drop occurs, so the grid immediately goes 203 volts negative. The equivalent circuit during the discharge is shown in (D) of figure 16-2. The voltage across r_{p1} (the tube's plate resistance) is 97 volts. The plate resistance r_{p1} is found by using the plate current and voltage when the grid voltage of V1 is zero.

$$r_{p1} = e_b/i_b = 97/10.3 \text{ ma} = \text{about } 9.4 \text{ K ohms}$$

In parallel with this (through the battery) is the 20-K plate load resistor. This parallel combination will have a resistance of about 6 K and will be in series with the 1-megohm resistor. For simplicity this 6-K resistance can be disregarded. This will introduce an error of less than one percent. The discharge time constant

ACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *	E1 to E2	E2 to E3	#† E3 to E4	# E4 to E5	† E5 to E6	† E6 to E7	† E7 to E8	† E8 to E9
SERVICE	4 mos. service—or completion of recruit training.	6 mos. as E-2.	6 mos. as E-3.	12 mos. as E-4.	24 mos. as E-5.	36 mos. as E-6. 8 years total enlisted service.	36 mos. as E-7. 8 of 11 years total service must be enlisted.	24 mos. as E-8. 10 of 13 years total service must be enlisted.
SCHOOL	Recruit Training.		Class A for PR3, DT3, PT3. AME 3, HM 3			Class B for AGC MUC, MNC.		
PRACTICAL FACTORS	Locally prepared check-offs.	Records of Practical Factors, NavPers 1414/1, must be completed for E-3 and all PO advancements.						
PERFORMANCE TEST			Specified ratings must complete applicable performance tests before taking examinations.					
ENLISTED PERFORMANCE EVALUATION	As used by CO when approving advancement.		Counts toward performance factor credit in advancement multiple.					
EXAMINATIONS**	Locally prepared tests.	See below.	Navy-wide examinations required for all PO advancements.				Navy-wide, selection board.	
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)		Required for E-3 and all PO advancements unless waived because of school completion, but need not be repeated if identical course has already been completed. See NavPers 10052 (current edition).					Correspondence courses and recommended reading. See NavPers 10052 (current edition).	
AUTHORIZATION	Commanding Officer		U.S. Naval Examining Center			Bureau of Naval Personnel		

* All advancements require commanding officer's recommendation.
† 1 year obligated service required for E-5 and E-6; 2 years for E-6, E-7, E-8 and E-9.
\# Military leadership exam required for E-4 and E-5.
** For E-2 to E-3, NAVEXAMCEN exams or locally prepared tests may be used.

Figure 1-2.—Active duty advancement requirements.

10904

10905

INACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *	E1 to E2	E2 to E3	E3 to E4	E4 to E5	E5 to E6	E6 to E7	E8	E9
TOTAL TIME IN GRADE	4 mos.	6 mos.	15 mos.	18 mos.	24 mos.	36 mos.	36 mos.	24 mos.
TOTAL TRAINING DUTY IN GRADE †	14 days	14 days	14 days	14 days	28 days	42 days	42 days	28 days
PERFORMANCE TESTS			Specified ratings must complete applicable performance tests before taking examination.					
DRILL PARTICIPATION	Satisfactory participation as a member of a drill unit.							
PRACTICAL FACTORS (INCLUDING MILITARY REQUIREMENTS)	Record of Practical Factors, NavPers 1414/1, must be completed for all advancements.							
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)	Completion of applicable course or courses must be entered in service record.							
EXAMINATION	Standard Exam	Standard Exam or Rating Training.	Standard Exam required for all PO Advancements.			Standard Exam, Selection Board. Also pass Mil. Leadership Exam for E-4 and E-5.		
AUTHORIZATION	Commanding Officer		U.S. Naval Examining Center			Bureau of Naval Personnel		

* Recommendation by commanding officer required for all advancements.

† Active duty periods may be substituted for training duty.

Figure 1-3.—Inactive duty advancement requirements.

10906

HOW TO PREPARE FOR ADVANCEMENT

What must you do to prepare for advancement? Advancement is not an overnight affair. One does not take the advancement examination and wake up in the morning in the next pay grade. There is a path or sequence of events which one must pursue. Certain things must be done or accomplished before one is admitted to the advancement in rate examination. You must study the qualifications for advancement, work on the practical factors, study the required Rate Training Manuals, and study other materials that are required for advancement. To prepare for advancement, you should be familiar with the purpose, use, and interrelationship of the following publications pertaining to the advancement process.

1. Manual of Qualifications for Advancement, NavPers 18068 (Series).
2. Record of Practical Factors, NavPers 1414/1.
3. Training Publications for Advancement, NavPers 10052 (Series).
4. Applicable Rate Training Manuals and their companion Enlisted Correspondence Courses.
5. Examinations for advancement.

Collectively, these documents make up an integrated training package tied together by the qualifications. The following paragraphs describe these materials and give some information on how each one is related to the others.

"Quals" Manual

The Manual of Qualifications for Advancement, NavPers 18068 (Series), gives the minimum requirements for advancement. This manual is usually called the "Quals" Manual, and the qualifications themselves are often called "quals." The qualifications are of two general types: military requirements, and professional (or technical) qualifications.

Military requirements apply to all ratings rather than to any one particular rating. Military requirements for advancement to third class and second class petty officer rates deal with military conduct, naval organization, military justice, security, watch standing, and other subjects which are required of petty officers in all other ratings.

Professional qualifications are technical or professional requirements that are directly related to the work of each rating.

Both the military requirements and the professional qualifications are divided into subject matter groups; then, within each subject matter group, they are divided into practical factors and knowledge factors. Practical factors are things you must be able to DO. Knowledge factors are things you must KNOW in order to perform the duties of your rate.

The qualifications for advancement and a bibliography of study materials are available in your educational services office. Study these qualifications and the military requirements carefully. The written examination for advancement will contain questions relating to the knowledge factors and the knowledge aspects of the practical factors of both the military requirements and the professional qualifications. If you are working for advancement to second class, remember that you may be examined on third class qualifications as well as on second class qualifications.

It is essential that the "quals" reflect current requirements of fleet and shore operations, and that new fleetwide technical, operational, and procedural developments be included. For these reasons, the qualifications are continually under evaluation. Although there is an established schedule for revisions to the "quals" for each rating, urgent changes to the "quals" may be made at any time. These revisions are issued in the form of changes to the "Quals" Manual. Therefore, never trust any set of "quals" until you have checked the change number against an up-to-date copy of the "Quals" Manual. Be sure you have the latest revision.

Record of Practical Factors

Before you can take the Navy-wide examination for advancement, there must be an entry in your service record to show that you have qualified in the practical factors of both the military requirements and the professional qualifications. A special form known as the Record of Practical Factors, NavPers 1414/1 (plus the abbreviation of the appropriate rating), is used to keep a record of your practical factor qualifications. The form lists all practical factors, both military and professional. As you demonstrate your ability to perform each practical factor, appropriate entries are made in the DATE and INITIALS columns.

Changes are made periodically to the Manual of Qualifications for Advancement and revised forms of NavPers 1414/1 are provided when

10907

a0e01

necessary. Extra space is allowed on the Record of Practical Factors for entering additional practical factors as they are published in changes. The Record of Practical factors also provides space for recording demonstrated proficiency in skills which are within the general scope of the rate but which are not identified as minimum qualifications for advancement.

If you are transferred before you qualify in all practical factors, NavPers 1414/1 should be forwarded with your service record to your next duty station. You can save yourself a lot of trouble by making sure that this form is actually inserted in your service record before you are transferred. If the form is not in your service record, you may be required to start all over again and requalify in the practical factors which have already been checked off.

A second copy of the Record of Practical Factors should be made available to each man in pay grades E-2 through E-8 for his personal record and guidance.

The importance of NavPers 1414/1 cannot be overemphasized. It serves as a record to indicate to the petty officers and officers supervising your work that you have demonstrated proficiency in the performance of the indicated practical factors and is part of the criteria utilized by your commanding officer when he considers recommending you for advancement. In addition, the proficient demonstration of the applicable practical factors listed on this form can aid you in preparing for the examination for advancement. Remember that the knowledge aspects of the practical factors are covered in the examinations for advancement. Certain knowledge is required to demonstrate these practical factors and additional knowledge can be acquired during the demonstration. Knowledge factors pertain to that knowledge which is required to perform a certain job. In other words, the knowledge factors required for a certain rating depend upon the jobs (practical factors) that must be performed by personnel of that rating. Therefore, the knowledge required to proficiently demonstrate these practical factors will definitely aid you in preparing for the examination for advancement.

NavPers 10052

Training Publications for Advancement, NavPers 10052 (Series), is a very important publication for anyone preparing for advancement. This bibliography lists required and recommended Rate Training Manuals and other reference material to be used by personnel working for advancement. NavPers 10052 is revised and issued once each year by the Bureau of Naval Personnel. Each revised edition is identified by a letter following the NavPers number. When using this publication, be sure that you have the most recent edition.

If extensive changes in qualifications occur between the annual revisions of NavPers 10052, a supplementary list of study material may be issued in the form of a BuPers Notice. When you are preparing for advancement, check to see whether changes have been made in the qualifications. If changes have been made, see if a BuPers Notice has been issued to supplement NavPers 10052.

The required and recommended references are listed by rate level in NavPers 10052. If you are working for advancement to third class, study the material that is listed for third class. If you are working for advancement to second class, study the material that is listed for second class. Remember that you are also responsible for the references listed at the third class level.

In using NavPers 10052, you will notice that some Rate Training Manuals are marked with an asterisk (*). Any manual marked in this way is MANDATORY—that is, it must be completed at the indicated rate level before you are eligible to take the Navy-wide examination for advancement. Each mandatory manual may be completed by passing the appropriate enlisted correspondence course that is based on the mandatory training manual; passing locally prepared tests based on the information given in the training manual, or in some cases, successfully completing an appropriate Class A School.

Do not overlook the section of NavPers 10052 which lists the required and recommended references relating to the military standards/requirements for advancement. For example, all personnel must complete the Rate Training Manual, Requirements for Petty Officer 3 & 2, NavPers 10056-B, for the appropriate rate level before they can be eligible to advance.

The references in NavPers 10052 which are recommended, but not mandatory, should also be studied carefully. All references listed in NavPers 10052 may be used as source material for the written examinations at the appropriate rate levels.

10908

Rate Training Manuals

There are two general types of Rate Training Manuals. Rating manuals (such as this one) are prepared for most enlisted rates, giving information that is directly related to the professional qualifications. Basic manuals give information that applies to more than one rate and rating. Basic Electricity, NavPers 10086-B, is an example of a basic manual, because many ratings use it for reference.

Rate Training Manuals are revised from time to time to keep them up to date technically. The revision of a Rate Training Manual is identified by a letter following the NavPers number. You can tell whether any particular copy of a Rate Training Manual is the latest edition by checking the NavPers number and the letter following this number in the most recent edition of List of Training Manuals and Correspondence Courses, NavPers 10061. (NavPers 10061 is actually a catalog that lists current training manuals and correspondence courses; you will find this catalog useful in planning your study program.)

Rate Training Manuals are designed to help you prepare for advancement. The following suggestions may help you to make the best use of this manual and other Navy training publications when you are preparing for advancement.

1. Study the military requirements and the professional qualifications for your rate before you study the training manual, and refer to the "quals" frequently as you study. Remember, you are studying the training manual in order to meet these "quals."

2. Set up a regular study plan. If possible, schedule your studying for a time of day when you will not have too many interruptions or distractions.

3. Before you begin to study any part of the training manual intensively, become familiar with the entire manual. Read the preface and the table of contents. Check through the index. Look at the appendixes. Thumb through the manual without any particular plan, looking at the illustrations and reading bits here and there as you see things that interest you.

4. Look at the training manual in more detail, to see how it is organized. Look at the table of contents again. Then, chapter by chapter, read the introduction, the headings, and the subheadings. This will give you a clear picture of the scope and content of the manual. As you look through the manual in this way, ask yourself some questions: What do I need to learn about this? What do I already know about this? How is this information related to information given in other chapters? How is this information related to the qualifications for advancement?

5. When you have a general idea of what is in the training manual and how it is organized, fill in the details by intensive study. In each study period, try to cover a complete unit—it may be a chapter, a section of a chapter, or a subsection. If you know the subject well, or if the material is easy, you can cover quite a lot at one time. Difficult or unfamiliar material will require more study time.

6. In studying any one unit—chapter, section, or subsection—write down the questions that occur to you. Many people find it helpful to make a written outline of the unit as they study, or at least to write down the most important ideas.

7. As you study, relate the information in the training manual to the knowledge you already have. When you read about a process, a skill, or a situation, try to see how this information ties in with your own past experience.

8. When you have finished studying a unit, take time out to see what you have learned. Look back over your notes and questions. Maybe some of your questions have been answered, but perhaps you still have some that are not answered. Without referring to the training manual, write down the main ideas that you have learned from studying this unit. Do not quote the manual. If you cannot give these ideas in your own words, the chances are that you have not really mastered the information.

9. Use Enlisted Correspondence Courses whenever you can. The correspondence courses are based on Rate Training Manuals or on other appropriate texts. As mentioned before, completion of a mandatory Rate Training Manual can be accomplished by passing an Enlisted Correspondence Course based on the Rate Training Manual. You will probably find it helpful to take other correspondence courses, as well as those based on mandatory training manuals. Taking a correspondence course helps you to master the information given in the training manual, and also helps you see how much you have learned.

80601 10908

10. Think of your future as you study Rate Training Manuals. You are working for advancement to third class or second class right now, but someday you will be working toward higher rates. Anything extra that you can learn now will help you.

SOURCE OF INFORMATION

One of the most useful things you can learn about a subject is how to find out more about it. No single publication can give you all the information you need to perform the duties of your rating. You should learn where to look for accurate, authoritative, up-to-date information on all subjects related to the military requirements for advancement and the professional qualifications of your rating.

Some of the publications described in this manual are subject to change or revision from time to time—some at regular intervals, others as the need arises. When using any publication that is subject to change or revision, be sure that you have the latest edition. When using any publication that is kept current by means of changes, be sure you have a copy in which all official changes have been made. Studying canceled or obsolete information will not help you perform efficiently or to advance; it is likely to be a waste of time, and may even be seriously misleading.

10910 . 1031

CHAPTER 2

NAVAL AIRCRAFT MAINTENANCE PROGRAM

Aircraft maintenance is the responsibility of the Aircraft Maintenance Department or the Operations Maintenance Division. The Aircraft Maintenance Department is, in most operating units (or activities), the largest department, and its primary efforts are expended toward supporting the unit mission. The Operations Department has the responsibility of carrying out the unit mission of flight operations (other than ferry or test flights) by Navy aircraft. In support of the unit mission, the objective of the Aircraft Maintenance Department is to maintain all assigned aircraft in a ready or "UP" status. An aircraft in an UP status is considered to be in a material condition of readiness to safely perform its intended mission and return to its base of operations.

All Aircraft Maintenance Departments are organized along the same general lines; that is, a standard organization is used throughout the Navy. The advantages of having a standard organization are readily apparent when one stops to consider what happens when aviation maintenance personnel are transferred between aircraft maintenance activities. The Aircrew Survival Equipmentman (PR) will find that the work centers have the same numbers and names; the officers will occupy similar billets as in the old outfit, though names and ranks will be different; and he will be performing essentially the same maintenance functions, using the same types of equipment and tools, procedures, and technical directives as before. In short, personnel newly received from another aviation maintenance activity can, in a very short time, be performing in their new unit as effectively as before without a lengthy indoctrination or break-in period.

This standard organization of Aircraft Maintenance Departments did not come about by accident, and it is not limited to the operating activity (squadron) level. Broad avenues of responsibility and certain guidelines are prescribed at the Department of Defense level and are based on years of aircraft maintenance experience by the Navy, Army Air Corps, and the Air Force.

The Naval Aircraft Maintenance Program is a part of the Navy Maintenance and Material Management System and is governed by the Naval Air Systems Command Instruction entitled the Naval Aircraft Maintenance Program (NAMP), NavAir Instruction 4700.2 (Series). All naval aviation activities performing aircraft maintenance and related functions base their policies, plans programs, and procedures on this instruction.

In the very early days of naval aviation, it was standard practice for every operating activity to perform their aircraft maintenance using whatever organization the commanding officer considered most expedient. Naturally, these organizations differed in varying degrees and in different ways. Most of these activities would likely be termed wasteful in the use of manpower, money, and material if their procedures were compared with modern maintenance procedures.

Much manpower was wasted, since technical training of personnel was left up to the squadron and was provided mostly on an on-the-job basis. Although effective maintenance was performed, maintenance techniques used by mechanics often varied with the individual. Of all the ways and means utilized to effect aircraft maintenance, one way would usually be the fastest and most reliable, but no provisions existed in the early days for determining which was the most desirable or for disseminating this information to all activities with a need to know. Centralized training, mandatory standardization of maintenance practices, engineering advances in research and development, and increasing use of machine accounting methods in Maintenance Data Reporting and Analysis have largely eliminated this problem.

10911

Not too many years ago the operating activities were self supporting; that is, they were provided with all the tools and equipment necessary for effecting all required maintenance short of overhaul. If more than one squadron was assigned to a ship or station, each had their full share of tools and equipment. It is evident that during a large part of the time, much of the equipment was not being used. Attempts at solving this problem led successively to the establishment of Carrier Aircraft Service Units (CASU's), Fleet Aircraft Service Squadrons (FASRon's), and finally the centralized local maintenance organizations of today—the Aircraft Maintenance Departments ashore and Air Wing/Group intermediate maintenance afloat.

The Aircraft Maintenance Departments and intermediate maintenance perform aircraft maintenance functions which are beyond the capability of the operating activities. Capability refers, not to the skill level of assigned personnel, but to the scope of the work assigned by the NAMP to the squadrons. In addition to maintenance work performed, the Aircraft Maintenance Departments provide material, together with the necessary facilities and support equipment, to the operating squadrons and units. This support to the squadrons aboard ship, as well as to the intermediate effort therein, is provided by the ship.

NOTE: It is common practice among maintenance personnel to refer to the station intermediate activity by its initials—AMD. In accordance with this common usage, AMD, as used in this manual, should be interpreted to mean the station Aircraft Maintenance Department.

In a similar manner, AIMD refers to the Aircraft Intermediate Maintenance Department aboard aircraft carriers.

The Naval Aircraft Maintenance Program is designed to provide for the greatest use of men, facilities, and materials. It further establishes a standard set of rules and regulations for the accomplishment of all maintenance on naval aircraft and associated equipment.

Whenever a new aircraft model is accepted for naval service, it is expected that these aircraft will fill a specific need for a given length of time. Enough men, facilities, and material for maintenance support of these aircraft for this length of time, are planned, procured, and assigned in accordance with where, how, and when these aircraft will be used. It is therefore mandatory that all naval aircraft maintenance personnel have a thorough knowledge of and abide by the maintenance program rules and regulations.

MAINTENANCE LEVELS AND RESPONSIBILITIES

The term "aircraft maintenance" has a very general meaning, ranging from a matter of minutes of squadron servicing to a matter of months of overhaul in an industrial type activity. More than the work or words, "maintenance" or "aircraft maintenance," is needed to indicate a specific meaning. The present military concept is to divide all aircraft maintenance functions into three distinct levels. The terms used to describe these levels are "Organizational Maintenance," "Intermediate Maintenance," and "Depot Maintenance."

ORGANIZATIONAL MAINTENANCE

Organizational maintenance is the type of work performed by the operating squadron or unit on a day-to-day basis in support of its own operations. Maintenance performed at this level includes (1) inspection, (2) servicing, (3) handling, (4) "on-aircraft" corrective maintenance including removal and installation of parts and components, (5) complying with technical directives (when prescribed), and (6) the necessary recordkeeping and reports peculiar to organizational maintenance.

Organizational maintenance in an operating activity is performed by permanently assigned personnel who are not responsible for intermediate maintenance. Organizational maintenance at naval air stations (on aircraft assigned to the station) is a function of the Operations Maintenance Division (OMD). The OMD also provides organizational maintenance and such other assistance to transiting aircraft as may be directed by higher authority.

INTERMEDIATE MAINTENANCE

Intermediate maintenance is that type of work performed in centrally located facilities for the support of operating activities within a designated geographical area, at a particular base or station, or aboard aviation ships. This level of maintenance includes shop type repair and test work on aircraft, components, and equipment from the supported units. Technical

10912

assistance, when required, is furnished by personnel of the Intermediate maintenance facility to the supported operating activities.

Intermediate maintenance activities are manned by a nucleus of permanently assigned personnel and designated Intermediate maintenance personnel temporarily assigned from the on-board tenant squadrons. When these squadrons deploy, their Intermediate maintenance personnel accompany their squadrons, and are then temporarily assigned to the AIMD if afloat or to the AMD at their new station.

NOTE: The Intermediate maintenance activity (AMD or AIMD) is commonly referred to as the supporting activity, and the Organizational activity (squadron) as the supported activity.

DEPOT MAINTENANCE

Depot maintenance is that type of work that must be done in an industrial type facility. Such facility may be either military or civilian. If the work is contracted out to a civilian concern, the type of work is still depot maintenance. This level includes overhaul and major repair or modification of aircraft, components, and equipments. It also includes the manufacture of specified aeronautical parts to be stocked as spares and the manufacture of kits for the accomplishment of aircraft and equipment modification. Installation of these spare-parts kits may be done at this or a specific lower level of maintenance.

Navy depot maintenance activities are manned primarily by civilians and are known as Naval Air Rework Facilities (NARF). However, some military personnel are usually assigned and assist with the intermediate and organizational type work necessarily connected with the depot facility.

It can be seen from the foregoing that the three aircraft maintenance levels or categories provide for an orderly separation of the various maintenance tasks. The bases for the separation are complexity of the task, equipment and space requirements, the skill level of assigned personnel, and the scope of support responsibility.

STANDARD AIRCRAFT MAINTENANCE ORGANIZATIONS

The aircraft maintenance organization supports naval operations by the upkeep of aircraft and associated support equipment to the assigned level of maintenance. This support is accomplished while adhering to the organizational principles and objectives as prescribed in the NAMP Manual, NavAir Instruction 4700.2 (Series).

Since all maintenance activities have similarities in mission, operation, and administration, it is only reasonable that they be standardized in these areas as much as possible. A standard maintenance organization, properly set up and administered, is designed to improve the following:

Performance and training of maintenance personnel.
Availability of aircraft for flight.
Safety.
Use of manpower and materials.
Planning and scheduling of the workload.
Management control of the organization.
Evaluation of work performance.
Combat readiness of the unit.
Continuity when aircraft and/or personnel are transferred between commands.

The foregoing objectives cannot be attained by means of a manual or an organization structure alone. They are attained by the sensible and conscientious efforts of all naval personnel engaged in the maintenance tasks, working harmoniously toward a common goal, under the management control processes used in the organization.

Specific functions of Aircraft Maintenance Departments include:

1. Periodic maintenance and routine inspection and servicing of aircraft, associated support equipment, and aeronautical material and components, including the necessary disassembly, cleaning, examination, repair, modification, test, inspection, assembly, and preservation.
2. Special work (when required) to comply with technical directives or local instructions.
3. Correction of aircraft and equipments discrepancies.
4. Assurance of high quality of all work.
5. Maintenance of required records and technical publications.
6. Maintenance and custody of tools and other equipment provided for use by the activity.
7. Training of assigned personnel. Most ratings, including the PR, will have already been provided with a satisfactory theoretical background for the performance of their assigned tasks. Further training in the practical

10913

aspects of aircraft maintenance is a continuing requirement.

8. Conducting of maintenance and ground handling safety programs.

9. Submission of reports for statistical, analytical, and historical purposes.

The depth and complexity of the specific functions in connections with the foregoing, vary in number and type of aircraft involved and the assigned maintenance level. Further coverage of aircraft maintenance organizations in this chapter is devoted primarily to the intermediate and organizational levels, as these are the basic levels to which NavAir Instruction 4700.2 (Series) is directed. Activities performing these levels of maintenance are also the ones to which most PR's are normally assigned.

An intermediate level maintenance department organization is illustrated in figure 2-1. An organizational level maintenance department (typical of a squadron or OMD) is illustrated in figure 2-2. The numbers shown in the blocks are work center codes. Work center codes are used in the Maintenance Data Collection System, which is an important part of the Navy Maintenance and Material Management System. Typical work centers are the maintenance office, aviators equipment branch, flight line, electronics branch of the avionics division, etc. Work center codes are necessary for recording and reporting work accomplished, since electric accounting machine methods are used for these purposes.

The organization for aircraft maintenance activities provides firm lines of authority from the Aircraft Maintenance Officer to the personnel accomplishing the work for which the activity is responsible. The term "department" is used in this training manual as a general term which applies equally to all maintenance activities having a department head. All major groups in the department which report directly to the department head are called divisions. Divisions are subdivided into branches. Branches may be broken down into sections and sections into units. (In OMD's, the Aircraft Maintenance Officer is a division officer of the Operations Department, and the divisions listed in figure 2-2 are then branches, etc.) Realinement of responsibilities and functions implied in figures 2-1 and 2-2, from one division to another or physical combination of divisions, is not authorized under current instructions. However, if the maintenance department/division has no responsibility for performing any of the

AM.3

Figure 2-1. —Organization chart for aviation activities performing intermediate level maintenance (ashore).

10914

without the 6-K resistance will be 0.001μf x 1 megohm = 1,000 microseconds.

Capacitor C2 discharges exponentially until the grid voltage of V2 is just above cutoff. Cutoff voltage for this tube with 300 volts applied is minus 18 volts as read from the characteristic curves. The cutoff period is terminated when the voltage drops to 18/203 or 0.089 of its initial value. The grid voltage is down to this value in 2.45 time constants, as calculated from the capacitor discharge curve on the universal time constant chart in Basic Electricity. Since the discharge time constant is 1,000 microseconds, the cutoff time equals 2.45 time constants multiplied by 1,000 microseconds or 2,450 microseconds.

The cutoff time for tube V2 will be 2,450 microseconds. Since the resistor and capacitor values are exactly the same, tube V1 will be cut off for 2,450 microseconds during the other half cycle of operation. The grid and plate voltage values and curves will also be identical. If a difference exists in the circuit of each tube, separate calculations must be carried out for each half cycle. In this case, 2,450 + 2,450 = 4,900 microseconds. The frequency at which square waves are produced is the reciprocal of the duration.

$$F = \frac{1}{4,900 \times 10^{-6}} = 204 \text{ cycles per second}$$

The duration and amplitude of the positive peak on the grid waveform can be readily calculated from the equivalent circuit shown in (C) of figure 16-2. The positive peak occurs as the capacitor is charged to a higher plate voltage. The capacitor charges through the resistance that consists of the plate load resistor for V1 and the grid to cathode resistance of V2. This is a total of 21K. The 1-megohm resistor carries only 0.1 percent of the charging current and is therefore safely disregarded. With the 0.001-μf capacitor the time constant is $0.001 \times 10^{-6} \times 2.1 \times 10^{4}$ or 21 microseconds. If the charge requires 5 time constants, the positive peak will disappear after a hundred microseconds.

The amplitude of the peak can be determined by using Ohm's law. The total voltage rise at the plate of V1 is 203 volts. This raises the grid voltage from cutoff (minus 18 volts) to some positive value. Since the first 18 volts of plate voltage rise changes the grid voltage to zero, the remaining rise above zero is 203 - 18, or 185 volts. This causes grid current to flow and the voltage to divide across the series combination of the grid to cathode resistance and the plate load resistance. As the grid to cathode resistance equals 1,000 ohms, and the plate load resistance equals 20,000 ohms, 1/21 of the 185 volts, or 8.8 volts, appears across the grid to cathode resistance. Thus the positive peaks at the grid will be 8.8 volts above zero.

Because the plate voltage cannot rise faster than the capacitor can charge, the plate voltage rise is exponential over a period of 100 microseconds. This rounds off the leading edge of the plate waveshape. The positive grid at the other tube causes a dip in plate voltage at that tube. The output from this circuit is normally taken from either plate although the grid voltage is sometimes useful.

In the chart (fig. 16-3) showing the effects of varying the sizes of the component parts of this circuit, the essential data is given, but the detailed and less important effects are omitted because of a lack of space. The effects of changing R_{L2}, R_{g2}, C2, and V2 are not listed since these effects are similar to those that result from changing R_{L1}, R_{g1}, C1 and V1 respectively—except that each effect occurs with the other half cycle of operation.

Improving Circuit Action

There are a number of slight changes that can be made in the basic plate coupled multivibrator circuit to improve its stability and output waveshape. One is to return the grids to a positive voltage, and another is to use series limiting resistors.

RETURNING THE GRIDS TO A POSITIVE VOLTAGE.—Returning the grids to a positive voltage improves the stability of a plate coupled multivibrator. In this arrangement, the grid-leak resistors are often connected to the source of plate voltage; in other words, the grids are returned to B plus. Under this condition the grid current flow causes the B-plus potential to exist mostly across the resistor while the grid to cathode voltage remains within a fraction of a volt or zero. When the plate voltage of the other tube drops, the capacitor discharges as usual, with a current that is high enough to drive the grid negative by the amount of the plate voltage drop. Due to this condition the exponential discharge of the capacitor appears as though the capacitor were charged to the plate voltage drop plus the plate voltage

1089

NOTE 1: WHEN RESPONSIBILITIES RELATIVE TO OPERATION AND MAINTENANCE OF GROUND SUPPORT EQUIPMENT ARE EXTENSIVE, THE COMMANDING OFFICER WILL ESTABLISH A GROUND SUPPORT EQUIPMENT BRANCH UNDER THE LINE DIVISION TO COORDINATE AND/OR CARRY OUT ORGANIZATIONAL MAINTENANCE FUNCTIONS ON ASSIGNED SUPPORT EQUIPMENT.

NOTE 2: IN MARINE CORPS ACTIVITIES THE AVIONICS AND ARMAMENT FUNCTIONS ARE SEPARATE DIVISIONS.

NOTE 3: WHEN RESPONSIBILITIES RELATIVE TO THE OPERATION AND MAINTENANCE OF AERIAL OR SURFACE TARGETS ARE EXTENSIVE, THE COMMANDING OFFICER WILL ESTABLISH A TARGET DIVISION.

AM.2

Figure 2-2. —Organization chart for aviation activities performing organizational level maintenance.

functions listed, the affected division or branch is allowed to be omitted from the activity's organization.

The organization structure provides for the Aircraft Maintenance Officer, with the aid of his subordinate officers, to manage the Aircraft Maintenance Department/division, and he is responsible to the commanding officer for the accomplishment of the maintenance activity's mission. He administers the operation of the department or division in accordance with controlling directives of higher authority concerning organization, reports, policies, procedures, workloads, and personnel complements.

Planning, control, and production are functional management responsibilities assigned the Aircraft Maintenance Officer. He and his subordinate officers must provide the direction and guidance essential for his subordinate echelons to implement and comply with all local and higher authority directives and maintenance policies. The Aircraft Maintenance Officer must estimate and program facilities, equipment, manpower, and training requirements.

The standard organization structure provides for the following subordinate officers to assist the Aircraft Maintenance Officer in the management of the organization:

1. The Assistant Aircraft Maintenance Officer to supervise the activities of the staff elements.

2. The Maintenance/Material Control Officer to exercise direct supervision over the production elements and material control.

10515

4fe01

3. Various aircraft maintenance division/branch officers to organize and manage in their respective functional areas.

ORGANIZATIONAL LEVEL

Organizational level maintenance activities are the prime users and operators of naval aircraft; therefore, most of their maintenance tasks involve day-to-day support for their own operations.

Organizational level activities are composed of maintenance managers who manage the activity; staff divisions which perform support type functions for the production elements; and production divisions which actually perform the various maintenance tasks.

Staff Divisions

Staff divisions are incorporated into the framework of Organizational level maintenance activities for the purpose of providing services and support to the production divisions, and of correlating the accomplishments and progress of the production divisions. Together, they provide the maintenance officer with a consolidated view of the current status of the maintenance picture.

A discussion of some of the more important functions of the staff divisions is contained in the following paragraphs. A more detailed discussion of these divisions and their responsibilities is contained in NavAir Instruction 4700.2 (Series).

The normal staff divisions in Organizational level maintenance activities are the quality assurance and analysis divisions.

QUALITY ASSURANCE DIVISION.—Quality assurance is fundamentally the prevention of the occurrence of defects. This includes all events from the start of the maintenance operation to its completion. Achievement of quality assurance depends on prevention, knowledge, and special skills.

Prevention is based on the concept that it is necessary to preclude maintenance failures. In the true sense, this principle extends to safety of personnel, to maintenance of equipment, and to virtually every aspect of the total maintenance effort. Prevention is concerned with the regulation of events, rather than being regulated by them.

Knowledge is derived from factual information. The NAMP introduces the practices of data collection and data analysis as means of acquiring this knowledge.

Special skills, not normally possessed by production personnel, are required in a staff of personnel trained in the techniques of data analysis and supervision of the quality assurance program.

The quality assurance program provides a systematic and efficient process for gathering and maintaining information on the quality characteristics of products and on the source and nature of defects and their immediate impact on the current operation. It permits decisions to be based on facts rather than on intuition or memory. It further provides comparative data which will be useful long after the details of the current occasion have been forgotten. The proper functioning of quality assurance requires the delegation of authority and the assumption of responsibility for action.

Teamwork must be achieved before benefits can be obtained from a quality assurance program. To be effective, quality assurance functions must blend with the interest of the entire organization. Each individual in the department must be permitted to use an optimum amount of judgment in the course of his daily work, since his judgment plays a vital part in the quality of his work. Quality assurance techniques supply each person, from the worker to the Commanding Officer, with information on actual quality achieved. This information provides a challenge to the individual to improve the quality of his work.

The quality assurance division provides the department head with information regarding the quality of work accomplished, points up areas that need particular attention, and develops more realistic inspection requirements. Among the primary functions performed by the quality assurance division are the following:

1. Establishes qualification requirements for quality assurance inspectors and collateral duty inspectors. (Quality assurance representatives are those personnel permanently assigned to the quality assurance division as inspectors. Collateral duty inspectors are those personnel permanently assigned to a production division who have a secondary or collateral duty assignment to inspect work accomplished within their assigned production division.) Reviews the qualifications of personnel nominated for these positions and endorses nominations to the department head. Maintains a record of all designated inspectors.

10916

2. Provides for the continuous on-the-job training of all inspectors in the techniques and procedures pertaining to the conduct of inspections.

3. Maintains the technical library for the department. Insures that each work center receives all publications applicable to their work areas, and that these are kept current and complete.

4. Reviews all incoming technical publications and directives affecting the department to determine their application to quality assurance.

5. Reviews publications and directives, such as Changes, Bulletins, Periodic Maintenance Requirements Manuals, etc. Prepares and submits recommendations for revision or change of these documents.

6. Prepares or assists in the preparing of Maintenance Instructions to insure that proper direction and emphasis is given to implementing quality assurance.

7. Reviews inspection records, flight records, and work records, and notes unnecessary or recurring discrepancies requiring special attention.

8. Insures that all work guides, checkoff lists, inspection forms, test flight forms, etc., used to define or control maintenance operations, are complete and current.

9. Insures that the configuration of aircraft, aircraft components, and support equipment are such that all essential modifications have been incorporated.

ANALYSIS DIVISION.—The analysis division provides qualitative and quantitative analysis information to the maintenance officer in order to enable him to continually review the management practices within his organization. Some of the functions performed by this division are related to quality assurance; therefore, the analysis division and quality assurance division usually work in conjunction with each other.

Maintenance data analysis functions are regularly assigned to personnel of the AZ rating. The size of the analysis division varies from one activity to another, dependent upon the size of the maintenance activity, number of aircraft maintained, etc. In activities performing Organizational level maintenance, this division normally consists of not more than three.

The primary responsibility of the analysis division is to monitor and control all procedures connected with the Maintenance Data Collection System (MDCS). It is the hub around which an activity's Maintenance Data Reporting System turns. The analysis division reviews and analyzes reports, produced by the MDCS, for information that is of benefit to the maintenance activity.

The general responsibilities of the analysis division encompass the extraction, examination, and presentation (in chart, tabular, or graphic form) of pertinent data from the MDCS reports. The requirements for these functions may stem from various sources and apply to a wide range of maintenance subjects. In some instances, analysis may be initiated to provide an answer to a specific problem. In other instances, analysis of selected areas of maintenance (for example, personnel utilization or productivity of work centers) may be initiated as a monitoring action.

Certain of the more important specific responsibilities of the analysis division are listed as follows:

1. Sort and arrange all source documents (cards and forms which contain data to be reduced, tabulated, and analyzed) prior to their delivery for key punching.

2. Collect and maintain in various forms all data needed to manage the maintenance effort.

3. Analyze and compare maintenance performance against maintenance plans and workload estimates.

4. Review maintenance data reports for significant variations from normal—isolate and identify the trouble areas revealed by these reports.

5. Assist the Aircraft Maintenance Officer and other supervisory personnel in developing new types of recurring machine-run reports deemed necessary for management of the maintenance effort.

6. Prepare briefs and explanations covering the content of the reports produced by the Maintenance Data Reporting System for presentation as required by the commanding officer, Aircraft Maintenance Officer, etc.

7. Identify and analyze material deficiencies, high manhour consumption areas, and study other pertinent trends.

8. Assist material control in relating the contents of monthly data reports to material consumption and forecasts for material.

9. Train work center personnel in proper methods of filling out documents, and assist supervisory personnel in the correct interpretation of resulting reports.

10917

10. Coordinate all the activity's data collection matters with the local machine accounting installation (Data Services), including the preparation of additional reports as required.

MAINTENANCE/MATERIAL CONTROL

Although the tasks performed by maintenance/material control may be considered a staff function to the Aircraft Maintenance Officer, the Maintenance/Material Control Officer exercises authority in a line position between the Aircraft Maintenance Officer and the production divisions.

The Maintenance/Material Control Officer is directly responsible to the maintenance officer for the management of the overall productive effort of the department. A recent reorganization of maintenance activities has placed the material control element directly under the Aircraft Maintenance/Material Control Officer. In order to separate the functions performed by maintenance/material control, it is divided into two work centers—one for the maintenance production control functions, and one for the material control functions. These are discussed further in the following paragraphs.

Maintenance Control Work Center

The space in which the personnel of this work center perform their functions is commonly referred to as maintenance production control, production control, maintenance control, or the maintenance control office. All of these terms are used synonymously in this training manual.

The maintenance control office is the nerve center of the entire maintenance department. As head of this office, the Aircraft Maintenance/Material Control Officer directs the production divisions. He is assisted in this task by the Maintenance Control Chief. The Aircraft Maintenance/Material Control Officer establishes and exercises control and coordination of the action of the production divisions to insure prompt movement of aircraft, parts, and materials and to promote harmony and cooperation. He maintains liaison with the supporting activity to insure that the department's productive capacity is kept compatible with workload requirements.

In discharging these responsibilities, the personnel assigned to the maintenance control perform the following functions:

1. Plan and schedule aircraft through all phases of assigned maintenance.
2. Initiate maintenance actions to the work centers for scheduled and unscheduled maintenance as required, assigning priorities and completion times.
3. Perform progress checks on work assigned.
4. Maintain an aircraft status board and keep cognizant divisions and work centers informed of the status of aircraft and related equipment.
5. Prepare necessary aircraft parking plans and movement schedules.
6. Maintain aircraft logs in accordance with current directives.
7. Insure that maintenance instructions are prepared when required, and provide the necessary control to insure compliance by work centers concerned.
8. Assign job control numbers for reported discrepancies.
9. Maintain the Organizational Maintenance Control Register.
10. Receive all completed source documents from the analysis division after processing and file for historical records.
11. Take necessary actions for reporting aircraft accounting data, aircraft engine accounting data, and other required reports.

Material Control Work Center

In order to maintain an effective aircraft maintenance program, a cooperative working relationship must exist between production and supply. Effective maintenance of complex weapons systems cannot be accomplished without an adequate material supply program. A material control work center is provided in the Organizational maintenance department organization to act as liaison between the maintenance department and the local supply activity.

The material control work center insures that proper parts, tools, and equipment are available to the production divisions in the required quantities at the proper time. The work center must compile and analyze maintenance usage data and furnish technical advice and information to the local supply activity on the identity and quantity of supplies, spare parts,

ereb10918

and materials necessary to accomplish the assigned workload.

The material control work center provides material support to the department by accomplishing the following functions:

1. Passes all requirements for material required for direct support of weapons system maintenance to the Supply Support Center.
2. Maintains a Material Control Register for all material requested in direct support of weapons system maintenance.
3. Maintains liaison with the supporting supply department on maintenance material matters to insure that material needs of the maintenance department are satisfied.
4. Initiates surveys in the event of loss, damage, or destruction of accountable items of material and equipment.
5. Establishes standard operating procedures which insure the inventory of tools and the adequate accountability of material and equipment.
6. Records and reports custody materials.
7. Performs certain cost and allotment record accounting, charting, and budgeting of costs.
8. Monitors the operation of toolrooms.
9. Obtains, controls, and reports authorized allowances of material.

This work center is also responsible for the maintenance of aircraft inventory logs/records for assigned aircraft. This includes the inventory of aircraft prior to transfer, upon receipt, and at other times, as required.

PRODUCTION DIVISIONS

Maintenance of naval aircraft involves the actual performance of maintenance tasks by mechanics and technicians. The production divisions are manned by such personnel. Although on an organization chart the production divisions are shown as the lowest element, this is not in keeping with their importance. If it were not for the production divisions, there would be no reason for the existence of any part of the organization.

The production element of Organizational level maintenance activities consists of three divisions as indicated in figure 2-2. These divisions may be subdivided into branches (as indicated) to more efficiently perform the required maintenance tasks. A discussion of some of the more important functions of the production divisions of an Organizational level maintenance activity is contained in the following paragraphs:

Line Division

The line division administers the Plane Captain Program. In addition, it is responsible for the maintenance which involves the day-to-day tasks and functions associated with actual flight operations, including participation in the FOD program. AMD's do not have a division which corresponds to the line division, since they do not operate aircraft. Preflight, postflight, and daily inspections, between-flight servicing and replenishment, responsibility for organizational level GSE, and the minor adjustment and checkout of installed aircraft equipment are examples of functions performed in this division. The line division coordinates and directs the troubleshooters, who are normally assigned from work centers in the other production divisions to accomplish correction of minor discrepancies.

Aircraft Division

The aircraft division coordinates and completes schedules (inspections) and unscheduled maintenance (major discrepancies which cannot be corrected by troubleshooters) of assigned aircraft. This division performs organizational maintenance tasks in the airframes, powerplants, and aviators equipment areas.

Avionics Armament Division

The Avionics armament division performs organizational maintenance tasks in the avionics and ordnance areas on assigned aircraft. This division provides personnel to the aircraft division as required to accomplish scheduled maintenance (inspections) on aircraft.

INTERMEDIATE LEVEL (ASHORE)

The primary purpose of Intermediate level maintenance is to support and supplement the work of Organizational maintenance activities. These functions are usually performed in centrally located areas for the support of operating aircraft on a shore station, aboard a ship, or within a designated area.

Intermediate level maintenance activities are not assigned aircraft for operational

10919

purposes; and their efforts are concentrated on the repairing and testing of aircraft components. Naturally, this requires a certain amount of record keeping and reporting.

The organizational structure of activities performing Intermediate level maintenance is, for the most part, closely related to that of an Organizational level maintenance activity. Because of their size and maintenance functions performed, Intermediate level maintenance activities are composed of more divisions than Organizational activities. As in the case of Organizational level activities, Intermediate level maintenance activities are composed of maintenance managers, staff divisions, and production divisions. An Intermediate level maintenance department organization, with assigned work center codes, is illustrated in figure 2-1. A discussion of the various divisions of an Intermediate level maintenance department is contained in the following paragraphs.

STAFF DIVISIONS

Staff divisions are incorporated into the organizational structure of Intermediate level maintenance activities for essentially the same reasons as they are in Organizational level activities—to provide services and support to the production elements. In addition to the two staff divisions previously discussed, Intermediate level maintenance activities have an administration division.

Administration

The administration division functions basically as the coordinator for all records and reports, directives, correspondence, and personnel matters for the department. It provides the department with such administration and clerical services as the reproduction, distribution, and routing of messages, directives, correspondence, and other forms of informational data. It implements directives concerning the distribution, retention, and disposition of records, reports, and logs. It controls the classified matter required by the department, establishes and coordinates the department training requirements, and obtains any school quotas needed to support these requirements. It acts as a liaison between the divisions of the departments, between the maintenance department and other departments of the organization, and between the maintenance department of its parent organization and the maintenance department of other organizations.

NOTE: In activities where the highest level of maintenance performed is Organizational, the standard organization does not provide for an administration division. In these activities, the administration functions are transferred to the assistant aircraft maintenance officer.

Administration division personnel accomplish the following specific functions:

1. Establish and control a central recordkeeping and reporting system for all maintenance reports and correspondence.
2. Implement all directives concerning distribution, retention, and disposition of records, reports, and logs.
3. Provide clerical and administrative services for the department.
4. Receive and control department correspondence.
5. Reproduce as necessary and distribute incoming messages and other data.
6. Maintain all correspondence and report files for the department, except those special reference files maintained by each division or branch.
7. Supervise and coordinate department administrative responsibilities with other departments/divisions as required.
8. Conduct liaison with the squadron or station administration department regarding maintenance department personnel matters.
9. Distribute personal mail to department personnel.
10. Make proper distribution of all nontechnical information and publications.
11. Publish and distribute approved locally issued maintenance directives, procedures, reports, and studies.
12. Control classified material required by the department.
13. Establish and coordinate the department training requirements. Obtain necessary school quotas to support these requirements.
14. Establish proper transportation and communication systems to provide complete support of the workload.
15. Assign spaces to the various divisions and establish the responsibility for security and cleanliness of such spaces.
16. Arrange department participation in joint inspections of facilities assigned to tenant activities especially incident to the departure of a tenant activity.

10920

Quality Assurance

The quality assurance division of Intermediate level activities has the same prime function as previously discussed—to preclude the occurrence of defects. This is accomplished in two ways: (1) Through statistical analysis to compare the results obtained with those desired, and (2) through intensive research to find methods of improving effectiveness of the overall maintenance effort.

The major concerns of the quality assurance division include the following:

1. Safety (of both personnel and equipment).
2. The need of maintenance personnel for training in the most efficient and effective methods and procedures.
3. The quality of workmanship and of materials used in maintenance.
4. The reliability of each equipment and its component parts, and of the procedures used in maintenance of the equipment.
5. Qualifications of all quality assurance personnel, including the collateral duty inspectors.

Analysis Division

As is the case in Organizational level maintenance activities, the analysis division in Intermediate level activities operates as a staff function to management. The functions performed by the analysis division in both levels of maintenance are practically the same; therefore, they are not discussed further in this section.

MAINTENANCE/MATERIAL CONTROL

Maintenance/material control in an Intermediate level activity is very similar to that previously discussed in an Organizational level activity; that is, it is divided into two work centers.

As the name implies, maintenance production control is the central control point of the entire maintenance effort. This is accomplished primarily by the proper planning, scheduling, and assignment of the various maintenance tasks performed within the maintenance department.

Intermediate level maintenance activities exist primarily for the purpose of supporting operating activities; therefore, the personnel working in the maintenance control work center are concerned with the procedures involved in planning and scheduling the workload which consists of repairing, testing, and processing aircraft parts, components, and related equipment. They perform some of the previously discussed functions; however, those concerning the scheduling of aircraft inspections, aircraft log book maintenance, and aircraft status board maintenance are not required in Intermediate level maintenance control.

Due to the size of Intermediate level activities, the location of the various work centers, and the number of components involved daily, it is not practical to control each component inducted into the activity from a central maintenance control area. Maintenance control delegates some of its functions to certain selected production divisions. Divisions so designated exercise direct control of the production efforts of assigned work centers, are responsible to maintenance control for the production efforts of the assigned work centers, schedule components into work centers, and assign priorities as directed by maintenance production control.

The segment of these selected divisions concerned with production control functions should not be confused with the production control work center depicted in figure 2-1. The production control work center in the figure is the overall coordinator for all division production control segments. The entire responsibility for production of the department is controlled by this work center.

Maintenance control cooperates with the staff members by utilizing their findings and recommendations to improve the overall maintenance effort. Together with the administration division, the analysis division, and the quality assurance division, maintenance/material control provides the Aircraft Maintenance Officer with a complete picture of the maintenance situation as it exists at a given time, and makes recommendations for improvement.

The functions of the material control work center of Intermediate level activities are closely related to those previously discussed under Organizational level. Since Intermediate level activities do not operate aircraft, their material control work center has no responsibility for aircraft inventory and inventory log/record maintenance.

The material control work center coordinates and controls the supply functions of the department. It acts as liaison between the

USN 0501 10921

department and the local supply activity, and it processes all supply and material transactions for the other divisions of the department. It requisitions material, maintains the Material Control Register, maintains inventories of materials on hand, maintains subcustody records of accountable items held by the department, maintains records of all material transactions, and accounts for the expenditure of funds by the department. It furnishes technical advice and information to the local supply activity concerning material requirements for the assigned workload.

The material control work center of Intermediate level maintenance activities has an aeronautical material screening unit which coordinates the screening of received materials and parts to determine the status and repair responsibility/capability.

PRODUCTION DIVISIONS

The standard organization framework for Intermediate level maintenance activities provides for six production divisions. (See fig. 2-1.) These production divisions are generally manned by personnel of the same rating; whereas, in Organizational level maintenance departments, personnel of more than one rating are grouped into fewer divisions. The type of work usually performed by an individual is the same regardless of the maintenance level at which he is working; that is, AD's work on engines and related equipment, AE's on instruments and electrical equipment, and AT's work on avionics equipment. The difference between work performed in production divisions at various levels lies in the depth of maintenance performed.

The production divisions provide intermediate level maintenance on aircraft components and equipment for the supported activities. Some of the more important responsibilities and functions of these divisions are described in the following paragraphs.

Powerplants Division

The powerplants division is manned by Aviation Machinist's Mates who perform maintenance on powerplants, powerplant components, and associated systems.

Airframes Division

Aviation Structural Mechanics are assigned to work centers in the airframes division. This division is responsible for the specified level of maintenance of the airframe and structural components; movable structures and surfaces including their hydraulic and pneumatic control and actuating systems and mechanism; air-conditioning, pressurization, visual improvement, oxygen, and other utility systems; and seat and canopy ejection systems and components.

Avionics Division

The avionics division is manned with the necessary combination of the following ratings to provide the required level of maintenance of avionics equipment for the supported activities:

Aviation Electrician's Mates maintain aircraft electrical and instrument systems.

Aviation Electronics Technicians maintain and test aviation electronic equipment including detection, reconnaissance, identification, communication, navigation, display, and special purpose equipment.

Aviation Antisubmarine Warfare Technicians maintain and test aircraft antisubmarine warfare (ASW) systems and equipment, including those related to magnetic anomaly detection, long and short range underwater detection, nuclei detection, integrated displays, and associated ASW equipment.

Aviation Fire Control Technicians maintain and test aircraft armament control systems, including fire control, automatic turrent control, and bomb director systems.

Aviators Equipment Division

Aircrew Survival Equipmentmen (PR's) are assigned to the aviators equipment division. This division is responsible for intermediate level maintenance as required in connection with parachutes, liferafts, lifevests, pressure suits, oxygen masks, emergency equipment kits, flight clothing, oxygen regulators, automatic parachute actuators, aviator's protective helmets, etc. AME's may also be assigned to this division for the upkeep and support of the oxygen system, pressurization and air-conditioning systems, and other emergency equipment as assigned within the scope of that rating.

Armament Equipment Division

Aviation Ordnancemen (AO's) are assigned to the armament equipment division and are

10923
10922

responsible for the maintenance of aircraft armament equipment and aviation ordnance equipment.

Support Equipment Division

The support equipment division is composed of personnel of the Aviation Support Equipment Technician rating who perform necessary maintenance on the support equipment assigned to the maintenance department and supported activities. Support equipment includes, but is not limited to, such items as test stands, workstands, mobile electric powerplants, and pneumatic and hydraulic servicing equipment.

INTERMEDIATE (AFLOAT)

A recent revision in aircraft carrier organization has established the Aircraft Intermediate Maintenance Department (AIMD). This department has the same basic responsibilities afloat as AMD's ashore, the accomplishment of intermediate maintenance in support of embarked aircraft and related equipment. In addition, the AIMD is responsible for Organizational maintenance functions relating to the ship's utility aircraft.

This department is headed by the AIMD Officer and consists of a nucleus of permanently assigned personnel and temporarily assigned maintenance personnel from the embarked squadrons and detachments.

The difference in the organizational structure of Intermediate maintenance ashore and afloat can be seen by referring to figures 2-1 and 2-3.

Some specific responsibilities and functions of the AIMD Officer include the following:

1. Administer the AIMD under the direction of the commanding officer in accordance with existing directives.

AD.12

Figure 2-3.—Intermediate level maintenance department organization (afloat).

10923

2. Manage the Intermediate maintenance effort performed in support of embarked aircraft including custody and upkeep of associated maintenance facilities and support equipment.

3. Assume Organizational maintenance responsibility for the ship's aircraft.

4. Provide and maintain aircraft maintenance facilities to support the embarked aircraft.

5. Update facility plans to accommodate deck load changes and new weapons systems.

6. Establish and update ship/wing/group personnel requirements in conjunction with the air wing/group maintenance officer to insure adequate manning for support of the Intermediate maintenance effort.

7. Maintain a current inventory of maintenance facilities and equipment and submit recommendations for changes to the Individual Material Readiness List.

8. Establish and maintain an effective training program and provide for training and licensing of personnel to operate support equipment.

9. Maintain and control a central technical library of publications for performance of Intermediate maintenance on embarked aircraft and assigned equipment.

10. Conduct maintenance/material planning conferences prior to and during deployments.

11. Assume responsibility for coordinating maintenance and security of all Intermediate and Organizational maintenance work spaces.

SUPPLIES

Nearly every maintenance task generates a need for supplies of one type or another. These supplies may consist of common everyday items like rags, screws, nuts, bolts, etc., or one of the many hundreds of aircraft or equipment components for which the PR has maintenance responsibility. If the job is to progress smoothly and if the assigned job completion deadlines are to be met, all material needs must be satisfied promptly.

A large number of aircraft and equipment components are reparable. For this reason, replacements for these items are not stocked to the depth that nonreparable items are stocked. In order to keep the supply of reparable items rotating from the shelves to the aircraft (or equipment) to repair and back to the shelves in an efficient and orderly manner, the turn-in of reparable items is stressed to the PR (and all other applicable aviation personnel).

The first part of this section provides a thumbnail sketch of the relationship of the PR and the local supply organization insofar as material procurement is concerned.

The second portion is devoted to handling and turn-in of reparable materials.

PROCUREMENT OF MATERIAL

Rapid communications is an integral part of the Navy Maintenance and Material Management (3-M) System. Every PR should be aware of all the means of rapid communications at his working area (center, station, etc.) and make use of them as necessary in obtaining needed parts or supplies. Such systems as 2-digit telephones, walkie-talkies, and intercoms are typical of the rapid communication systems at various stations. Using such systems greatly reduces the elapsed time between ordering and receiving a part or parts. The PR should use whatever means is available to let his needs be known.

Procedure

When the need for a part becomes evident to a PR who is working at a maintenance task, he immediately notifies his work center supervisor. The work center supervisor in turn notifies the maintenance control chief, requesting a priority. The supervisor then relays the need for the material to material control. Material control, in turn, informs the local supply support center. As knowledge of the need for this part is being pushed along from the worker to the supply activity, each place along the line of communications adds some information. For instance, the worker tells his work center supervisor the name of the part and the quantity needed. The work center supervisor looks up the part number and upon notifying the maintenance control chief tells him that so many of such and such an item is needed for job control number so and so. The maintenance control chief assigns a priority for the material. The work center supervisor then communicates with the material control division and gives them the following information: Name of needed part, part number, job control number, aircraft bureau number/serial number, quantity required, and delivery point. The material control division enters the necessary information

10924

CHANGE	FREQUENCY	AMPLITUDE OF e_{b1}	DURATION e_{b1} AT E_{bb}	AMPLITUDE e_{b2}	DURATION e_{b2} AT E_b	WAVESHAPE CHANGE ——— BEFORE CHANGE -------- AFTER INCREASE

Figure 16-3. —Effects of varying elements in multivibrator.

supply. The net result is that the curve shown in figure 16-4 (A), resulting from the negative peak value to cutoff, is much more linear due to the fact that a smaller percentage of the discharge curve is used.

Returning the grids to a positive voltage produces an advantage in that the discharge curve strikes cutoff at a more nearly vertical angle. This means that if variations of voltage or temperature in the circuit affect the relation of the waveshape to the cutoff value only a small change of time will occur. In contrast, study the grid voltage curve in (B) of figure 16-4 where the grid resistor is grounded. The discharge curve is almost parallel at the cutoff value. In this case a small variation of the cutoff value will cause a large time change. In conclusion, then, returning the grids to B plus decreases the CHANGE in duration of pulses and the free-running frequency for a given change in circuit constants.

You can increase your understanding of the effect of returning the grid to B plus by making quantitative analyses and studying equivalent circuits. In figure 16-5 (C), notice the equivalent charging circuit of C1 during the time that V1 is conducting. In (B), the parts of the circuit involved during the charge of C1 are shown. Since the grid to cathode resistance is very small, compared to the grid-leak resistor, it can be represented as a direct connection, producing the equivalent circuit in (C). Here R2 is relatively small; as a result the capacitor will be fully charged before tube V2 starts to conduct. Thus, while V2 is cut off, capacitor C1 has a charge of 300 volts.

The discharge circuit for C1 is shown in (D). V2 is brought into conduction at this time, causing a 203-volt drop across the load resistor R2. A closed circuit is formed as shown in (E). The voltage across the load resistor may be considered as a source of voltage or battery which is of a polarity to aid the capacitor in causing current flow. The total voltage across the resistor R3 becomes the capacitor charge plus the load resistor voltage (300 + 203 = 503 volts). The grid end of resistor R3 is 503 volts negative with respect to the end connected to 300

1090

in their register, then informs the local supply support center (SSC) of the number of the part, the priority, and the designated delivery point.

When the material is available locally (on hand in supply), the maximum time allowed for processing and delivery is usually as follows:

Priority	Process/Delivery Time
1-3	1 hour
4-8	2 hours
9-20	24 hours

If needed materials are not available on station, the supply department transmits these needs off station through the proper channels to insure prompt service and follows up on such orders as necessary.

A branch of the local supply support center, the supply response section (SRS), is responsible for delivering the required material to the delivery point designated by the supported organization. In most cases in which no delivery delays are encountered, the needed material is delivered directly to the worker at the job site.

Naturally, there is paperwork involved, but this is taken care of by the supply support center in due time after or while the part is being delivered. The main thing is that the part is not delayed anywhere in the line of communications by paperwork.

The usage of a part or of supplies generally governs how fast it can be placed in the hands of the man on the job. For common items of hardware, rags, etc., the local supply activity maintains stocks in the vicinity where maintenance is being performed. These are known as preexpended stocks; that is, they are written off on their accounts just as if they had been issued, and the mechanics can pick up the desired quantity of these items as soon as they need them. When the stock gets low, the supply activity preexpends another batch and restocks.

For fast moving reparable items of aircraft and equipment parts, an adequate stock is kept more readily available than for slower moving items. In some cases, such items may be positioned in a roving van or pie wagon which maintains constant touch with the supply activity by a 2-way radio. In such cases, delivery of a needed part can be accomplished in a matter of minutes.

Material Turn-In

As mentioned previously, it is often necessary that defective parts be turned in to supply. Such parts are known as accountable items; and whenever one is issued for installation, the removed item must be turned in within 2 days. The PR is not normally responsible for the physical return of the item. Defective accountable items are picked up by a representative of the supply department's supply support center for delivery to the local intermediate maintenance activity.

The defective item, if within the repair capability of the IMA, is repaired and returned to the supply department in an RFI condition. If the defective item cannot be repaired by the IMA, it is forwarded to the supply screening section of the supply support center for transfer to the appropriate depot level of maintenance. The IMA may consider the defective item beyond economical repair and may forward the item to the supply screening section, recommending survey or salvage.

NAVY MAINTENANCE AND MATERIAL MANAGEMENT (3-M) SYSTEM

The 3-M System was established to insure maximum readiness and reliability at the lowest cost in men, money, and material throughout the Navy. It has application to both ships and aircraft.

NOTE: Throughout this training manual when reference is made to the 3-M System, it concerns only the naval aviation portion of the system.

The 3-M System is sponsored and directed by the Chief of Naval Operations (CNO), administered through the operating chain of command, and provided material and technical support by the Naval Material Command. In reality, the 3-M System provides maintenance managers information required for efficient and economical utilization of human and material resources in the performance of aircraft maintenance. This system insures that maintenance personnel, equipment, and facilities are utilized to the fullest extent in actual aircraft and related equipment maintenance performance.

The 3-M System includes two broad areas: (1) A planned maintenance system (PMS), and (2) a Maintenance Data Collection System (MDCS).

Through the use of the PMS it is possible for operating and maintenance activities to achieve and maintain maximum operational

Seq of 10925

efficiency of all aircraft and related equipment at all times, reduce down time of equipments to the minimum consistent with good maintenance practices, and reduce the cost of maintenance on both manhours and money.

The PMS systemizes the conduct of the various required aircraft inspections by combining, in convenient sets of Maintenance Requirements Cards (MRC's) for each type aircraft, information required by the workers to accomplish the inspections. These MRC sets are based on information contained in the Periodic Maintenance Requirements Manual (PMRM) for the type of aircraft concerned.

Together, the PMRM and MRC's tell what inspections have to be performed; when and how they should be performed; what skills, tools, and special equipment are required to perform them; what safety precautions should be observed; and in what sequence individual inspection actions should be accomplished.

The Maintenance Data Collection System is the second area covered by the 3-M system. It is actually a maintenance and material management control and information system, which includes maintenance data reporting among other things. It was designed to provide a means of recording maintenance actions in sufficient detail so that a great variety of information may be retrieved concerning maintenance actions and the performance of equipment involved. The system also provides data concerning the initial discovery of malfunctions, how equipment malfunctioned, what equipment was involved, what repair parts and materials were used in the repair process, how assigned manhours were utilized, and aircraft flights and readiness data.

The MDCS includes three major categories of data recorded by maintenance personnel and collected for machine processing. These categories are manhour data, maintenance data, and aircraft statistical data.

NOTE: Manhour accounting and maintenance data collection system forms (source documents) are discussed in detail later in this chapter.

AIRCRAFT MAINTENANCE FORMS AND RECORDS

Forms and records are used for many purposes in naval aviation maintenance. Various kinds of information about each flight are required to be recorded. This type of information is useful for the reduction of operational, maintenance, personnel training, aircraft utilization, and aircraft historical data. Other forms and records are used to specify what maintenance is to be performed on aircraft and who is to perform it; and when the maintenance is completed, form the basis for establishing credit for an outstanding job or fix responsibility for poor work.

This chapter deals with the most common forms and records with which the PR is concerned in his day-to-day duties.

NAVAL AIRCRAFT FLIGHT RECORD

The Naval Aircraft Flight Record is a four-part, four-page record that is completed for every flight of naval aircraft. This form, printed on yellow paper, is familiarly known as the yellow sheet. In fact, the usage of the term has been so widespread and long continued that the words "Yellow Sheet" are printed at the top of the first page of the form to help identify it.

Of the four parts of this record, the PR, when and if he is assigned as plane captain, will be primarily concerned with only Part A—Preflight. After inspecting and servicing his aircraft and before the arrival of the pilot at the aircraft, the plane captain initiates the yellow sheet for the next flight.

In Part A he enters in the appropriate spaces the date, aircraft model, its bureau number (BUNO), and its side number. NOTE: The bureau number is a number assigned to the aircraft by the Naval Air Systems Command upon acceptance of the aircraft. This number remains with that aircraft until it is stricken from the Navy inventory and is not thereafter assigned to another aircraft. The aircraft side number (also termed the squadron number, local number, or modex) is used for local identification, since each squadron in a Group or Wing utilizes a different series of side numbers.

Also included in Part A to be filled in by the plane captain are spaces to identify the aircraft's reporting custodian (the activity to which the aircraft is assigned), the grade and quantity of fuel and oil aboard, the kind and quantity of ordnance and pyrotechnics aboard, and the aircraft's flight limitations. Local instructions always govern the specific content of the aircraft limitations space and this information is always available to the plane captain for copying in this space.

10926

There is a space on Part A for the plane captain to sign, also furnishing his rate. The plane captain thus certifies that the aircraft has been inspected that day in accordance with approved preflight instructions, is serviced as stated on the form, and is ready for flight. NOTE: Daily and preflight inspections are performed in accordance with the applicable set of Maintenance Requirements Cards (MRC's).

The plane captain also fills in basic information pertaining to date, model, BUNO, side number and reporting custodian wherever it appears in the other parts of the form.

Part A of the yellow sheet is always retained at the place of first takeoff of the flight. The other parts may or may not accompany the aircraft, depending upon where the flight is to terminate and local policy.

At the completion of the flight, the pilot fills in the applicable portions of Part B—Maintenance. The pilot's action may be limited to circling an arrow to indicate that the aircraft is still in an UP (flyable) status with no minor discrepancies and signing it. Or, he may list one or more discrepancies, numbering them in numerical order. If any of the discrepancies DOWN the aircraft, he circles the DOWN (unsafe for further flight, pending corrective action) arrow and indicates each grounding discrepancy by making an X in the column alongside the number of the discrepancy.

Whenever a pilot reports aircraft, system, or equipment discrepancies on Part B of the yellow sheet, they must be corrected. Normally, Maintenance Control issues necessary authority to the appropriate shop(s) for the accomplishment of the necessary work and initiation of the Maintenance Action Form. As each discrepancy is completed, it is entered in the "Corrective Actions Accomplished" section of Part B. Each corrective action entry is numbered to correspond with the discrepancy number. Whenever the maintenance action corrects a grounding discrepancy, the pilot's X, which identifies the discrepancy, is circled. This system provides supervisory personnel with a quick method of determining the number of outstanding grounding discrepancies against an aircraft.

When all grounding discrepancies have been corrected; it may be possible to again place the aircraft in an UP status. Of course, it is possible to have several minor discrepancies against an aircraft, no single one of which justifies downing it, yet when taken collectively, they can amount to a serious liability if the aircraft is flown.

Parts C and D of the Naval Aircraft Flight Records are used to record aircraft, engine, and accessory operating time and operations data, respectively.

MAINTENANCE INSTRUCTIONS

A single type of maintenance instruction form is used to promulgate the three kinds of maintenance instructions required by the Naval Aircraft Maintenance Program. A checkbox area at the top of the page is used to indicate the kinds of maintenance instruction being issued in each case. The three kinds of maintenance instructions are discussed in the following paragraphs.

Single Action Maintenance Instruction

The Single Action Maintenance Instruction (SAMI) is issued when work of a one-time nature is to be performed on aircraft or equipment. The work ordered is of such a nature that it will not thereafter need to be performed again on the same aircraft. An example is an Airframe Change issued for all aircraft of a particular model. The SAMI itself is not authority to proceed with the work. It merely specifies what has to be done and, when applicable, has appended to it all the necessary references, directives, and other information.

Compliance with a SAMI is accomplished by Maintenance Control making an entry in their maintenance control register and then relaying the job control number along with other pertinent facts to the work center supervisor concerned. The work center supervisor makes his entries on the work center's register and assigns men to comply with the SAMI. Verification of completion of the task along with the manhours expended are documented on the Maintenance Action Form (MAF).

In areas where technical directives are to be incorporated, compliance is accomplished by Maintenance Control issuing a Technical Directive Compliance Form (TDC). This form initiates the maintenance action, verifies completion, and accounts for the manhours expended.

Using a SAMI to describe the work and verbally initiating the action on each aircraft simplifies the MAF preparation, standardizes logbook entries, and results in more orderly

10927 19350

scheduling of the necessary work among all applicable aircraft assigned. Figure 2-4 illustrates the maintenance instruction prepared as a SAMI.

Continuing Action Maintenance Instruction

A Continuing Action Maintenance Instruction (CAMI), as its name implies, is a local directive providing instructions for the performance of work which is or may be of a continuing nature. Like the SAMI, it is not authority needed to proceed with the work. Here too, a Maintenance Action Form reports compliance with the directive. Examples of work properly covered on a CAMI are (1) the accomplishment of minor inspection and cleaning of a component after a given number of flight hours; and (2) a special inspection which must be performed on a conditional basis; i.e., an airframe inspection if and when the aircraft has been subjected to a hard landing.

Technical Information Maintenance Instruction

Technical Information Maintenance Instruction (TIMI's) are issued by local maintenance activities to promulgate technical information within that activity only. Issuance of a TIMI does not involve the accomplishment of work; however, the information contained is sustaining in nature. Typical of instances where TIMI's may be issued are (1) precautions in handling of certain chemicals, (2) changes in specification materials, and (3) changes in service life of explosives or soft goods.

MAINTENANCE ACTION FORM (MAF)

This section outlines the procedures for documenting maintenance actions using a single and multicopy Maintenance Action Form. A maintenance action is any corrective or preventive action taken to maintain or restore equipment or material to a satisfactory operating condition. This action consumes manhours or material, or both.

The Maintenance Action Form is originated in the work center. Whenever the work center supervisor is notified of required work, he enters this information in the work center register and assigns men to the job. Upon completion of the work the worker or crew leader fills out the MAF, using information from the supervisor's work center register and verifies completion of the work, manhours expended, materials used, etc. Whether the worker uses the single copy MAF or the multicopy MAF depends upon whether a reparable item is removed from the aircraft. The single copy MAF (fig. 2-5) format is identical with the multicopy form. The uses of the two MAF's are discussed later in this chapter.

Referring to figure 2-5, completion of the numbered and lettered spaces is discussed in the following paragraphs.

Job Control Number (JCN). The Job Control Number is a 10- or 11-character "number" that serves as a base for maintenance data reporting and maintenance control procedures. The JCN provides separate identification of each maintenance action, when necessary. It also identifies the maintenance actions accomplished by intermediate maintenance activities in support of organizations or an organizational discrepancy. The four parts of the JCN are organization code, date code, sequence number, and suffix and are thus explained.

The organization code is a 3-character code composed of letters and numerals (alphanumeric) which identifies an organization. This part of the JCN is published by higher authority for each individual activity performing or which is responsible for aircraft maintenance and always remains constant within the activity.

The date code identifies the date on which the JCN was initiated or assigned to a job. Therefore, this is not necessarily the date on which the work was actually started. NOTE: The date code, known as the Julian date, identifies the year and the numerical day of the year and consists of four numbers. The first number indicates the last digit of the calendar year, the next three numbers specify the number of days in the calender year which have elapsed since January 1 of that year; for example, the Julian date 5350 identifies the 350th day of 1965 or, in more familiar terms, 16 December 1965; 6006 is the 6th day of 1966. All dates used in the Maintenance Data Reporting Program are reported in Julian dates since any date in any 10-year period can be shown in just four digits. Encoding the date in this manner simplifies recordkeeping and data reduction by machine methods.

The sequence number part of the JCN (identified SER on the form) is either a 3-digit

PR.106

Figure 2-5.—Maintenance Action Form.

10930

number that runs consecutively from 001 to 999 or a 3-character alphanumeric code with an alphabetic first character and two numbers which run from 00 to 99. The sequence number is normally assigned in sequence as new jobs come up. When the number 999 (or alphanumerically, 99) has been assigned, the next number in sequence is again 001. The alphanumerical sequence numbers are used only when documenting calendar inspection maintenance actions.

The JCN suffix is a single alphabetic character which is added to the basic JCN (those parts just discussed) to identify a subcomponent repair job which was done separately from the major repair job. This code applies to intermediate maintenance only. An example of this is when a defective item is replaced with a good one during the course of a major job. The MAF Job Control Number used to process the removed part through repair (intermediate) maintenance would be the same basic code as the major job but the suffix A would be added to identify the subcomponent repair.

Type Equipment. The type equipment code is a 4-character code consisting entirely of letters. The type equipment code on the MAF shown in figure 2-5 is the code for the A-4E aircraft. These codes are listed in official directives and are mandatory for use.

Bu/Ser No. A bureau number or serial number is a number that identifies a specific end item or component, including aircraft and their components. The number is usually assigned by the manufacturer (serial numbers) or the Navy (bureau numbers), and is used to differentiate between a given end item and others of the same type, model, series, design, etc.

Action Org. Entered here is the organization code number of the organization performing the work. In case the same organization that assigned the JCN is performing the work, the code entered is the same as the organization code in the JCN.

Work Center. Entered here is the work center code of the work center accomplishing the maintenance action described on the MAF. This is either (1) the code of the worker's assigned work center, or (2) if temporarily assigned, the code of the work center to which he is temporarily assigned.

Maintenance Level. Entered here is a checkmark in the block which describes the level of maintenance being performed. This information should not be confused with organizational assignment of personnel. For instance, a man assigned to an intermediate maintenance activity may actually work on an aircraft. Such a job would normally be considered as organizational level work. As a general rule, all work performed on aircraft or missiles is considered as organizational level maintenance and work performed off the aircraft or missile as intermediate level maintenance.

Action Date. Entered here is the Julian date on which (1) the action is completed, or (2) the MAF is turned in to account for manhours accumulated against a job, or (3) the job is turned over to another work center, or (4) a job is interrupted due to the fact that supply must go off station for parts, or (5) a reporting period ends.

Work Unit. The work unit code is a 5- or 7-character alphanumeric code which normally identifies the system, subsystem, component and part of the end item being worked on. Work unit codes are published by the NavAirSysCom in Work Unit Code Manuals for end items in two major categories: Type/model/series for aircraft, drones, and missiles; and aircraft maintenance support equipment. Five-character work unit codes from these manuals are used to code all work on an end item and its components. The sixth and seventh characters are used in benchwork (off equipment) to allow identification of reparable subassemblies of major components.

When Discd. When discovered codes are single alphabetic characters which identify when the need for maintenance was discovered. These codes are applicable to the MAF only. There are two sets of when discovered codes, covering the following equipment categories: Aircraft and engines and aircraft maintenance support equipment.

When discovered codes relate primarily to conditions under which the malfunction or discrepancy was discovered rather than to the time in days or hours. For instance, code F (aircraft and engines) identifies a discrepancy or other need for maintenance that was discovered during the pilot's weekly inspection, while code F (aircraft maintenance support equipment) indicates that a need for additional maintenance was discovered during a period of unscheduled maintenance on the support equipment.

Type Maint. The type maintenance code is 1-character alphabetic code used to describe the type of work being accomplished (i.e., scheduled, unscheduled, supply support, etc.).

Definitions and explanations of all these codes are contained in an appendix to the Navy Maintenance and Material Management Program Manual.

Action Taken. The action taken code is a 1-character alphabetic or numeric code which describes the action that has been taken to correct the discrepancy. The action taken code A (discrepancy checked, no repair required) is used only in those cases where an inspection or operational check has been performed and the reported trouble cannot be duplicated or does not exist. In these cases the Malfunction Description Code is 799 (no defect) rather than a code that describes the reported discrepancy.

MAL. (Malfunction Description). The malfunction description code is a 3-character numeric code used to describe the malfunction occurring on or in the item identified by the work unit code on the Maintenance Data Reporting Forms. These codes are listed in alphabetical and numerical sequence in all Work Unit Code Manuals.

Items Proc. (Items Processed). Items processed, for the purpose of Maintenance Data Reporting, is defined as the number of times that an action indicated by an action taken code is applied to the item identified by the work unit code recorded on an MDR form, or the number of times a support action is accomplished. EXAMPLE: Since the fuel nozzle of a jet engine is a coded item, replacement of five fuel nozzles would be documented as five items processed. In contrast to this, replacement of several tubes in an electronic assembly would be documented as one item processed with the work unit code identifying the electronic assembly being repaired, and the action taken code indicating repair.

Manhours. Entries in the manhours block of the MAF forms represent all manhours expended by assigned personnel in completion of the work described on the source document. Hours and/or tenths worked multiplied by the number of men working equals total manhours. Time expended in exceptions of three-tenths of an hour or less is included in the total labor hours for the job. Exceptions which exceed three-tenths of an hour are not accounted for on Maintenance Action Forms. They are charged to the proper labor distribution code in the Manhour Accounting System described later in this chapter. Entries in the manhour block of the Maintenance Data Reporting (MDR) forms do not include labor hours for any work center other than the one submitting the document. For example, if two work centers jointly correct a discrepancy (same JCN) on the same aircraft or equipment, workers from each work center submit a source document with that particular work center's labor hours in the manhour block.

EMT. (Elapsed Maintenance Time). Elapsed maintenance time is defined as the actual clock time, in hours and tenths, that maintenance was being performed on a job. Although the EMT is directly related to job manhours, it is not to be confused with total manhours required to complete a job.

Block 16. Left blank. Use of this block is not currently prescribed.

Removed Item. This block is completed on the 4-part MAF when a reparable item is removed from the aircraft or equipment being worked on. Also entered in this block is the serial number of the removed item and the manufacturer's code, and part number. METER READING in this block refers only to those items which have a meter or clock installed. Entered here is the number of starts, cycles, hours, etc., if applicable. If no meter is installed, no reading entry is required.

Installed Item. The component serial numbers of the installed item is entered here. Also, the manufacturer's code, serial number, and part number are entered.

NOTE: The removed and installed item blocks on the single copy MAF should be completed when recording cannibalization actions or when removing or installing items on the configured item lists. Configured items are selected items which require configuration accounting. Any item which meets one or more of the following criteria may be selected as a configured item.

1. An item which affects mission capability and can be interchanged with a similar item.
2. Management attention items.
3. Items with Accessory Record Cards. (See Aircraft Logbook.)

Discrepancy. A narrative description of the reported discrepancy or work to be performed is entered in this space. The appropriate arrow below the word DISCREPANCY is circled to indicate the flying status of the aircraft.

Corrective Action. A narrative description of the work accomplished in compliance with the discrepancy block is entered here by the person accomplishing the job.

10932

Entries Required. Applicable checkmarks in the entries required space are made when the action or discrepancy requires logbook or accessory record card entries. Maintenance Control enters a checkmark in the configuration block when configuration of the equipment is affected. The person making the entries signs his name and rate in the adjacent signature block.

Corrected By. The worker or crew leader who accomplishes or supervises the repair signs his name and rate in this block.

Inspected By. The quality assurance or collateral duty inspector who inspects the job for proper standards signs his name and rate in this block.

Supervisor. The work center supervisor or his assistant signs his name and rate in this block to indicate that screening and other appropriate action has been accomplished.

Repair Cycle Data. Enter the Julian dates for 1. Removed; 2. Received Material Control; 3. Work Started; and 4. Completed. Check the appropriate block to indicate if the item is Ready for Issue (RFI), Requires Rework (B COND), or is Recommended for Survey or Salvage (R/S).

During the actual repair, if the job is interrupted for one or more days due to a lack of parts, enter the Julian date that the job goes AWP (awaiting parts) adjacent to block 5 or 7. Enter the Julian date that the parts are received adjacent to block 6 or 8. Blocks 5 and 6 are used the first time the job status is AWP and blocks 7 and 8 are used the second time the status is AWP. If the job status is AWP more than twice, dummy dates within the actual repair time are entered adjacent to blocks 7 and 8 to reflect the actual number of days lost due to the second and subsequent AWP status.

Failed Material. On the single copy MAF, enter the action taken code, malfunction description code, quantity, manufacturer's code, and part number of failed material in this block if the parts replaced during repair are parts, bits, and pieces that have failed in a major component. If the failed item is removed and replaced, enter Action Taken code R (removed and replaced). If the removed item is removed, repaired, and reinstalled, at the organizational level of maintenance, enter action taken code C (repaired). It is intended that this block be utilized to record only primary items that have failed. It is not intended to be used for recording all items replaced (i.e., common hardware, nuts, screws, safety wire, etc.), nor is it to be used to record routine replacement of seals, gaskets, washers, fittings, etc., that are installed during overhaul or repair.

Accumulated Hours. The work centers use this block to record manhours and elapsed maintenance time (EMT) accumulated against a job. Whenever (1) completing a repair action, (2) turning in a supplementing document in support of the job, (3) making a work center change, (4) a reporting period ends, or (5) going AWP, manhours and EMT are totaled in this section and entered in blocks 14 and 15 (near the top of the MAF) of the submitted document, after which the entries in the accumulated hours block are lined through to indicate they have already been documented.

Required Material. Whenever material is required to complete a maintenance action, it is requisitioned and a line for each item ordered is filled in in this section. Entered are the requisition number, manufacturer's code, part number, quantity, priority, date and time the material was ordered, and date and time the material was received.

Single Copy MAF

A single copy MAF is used to document the following actions:

1. Repair work on the equipment which does not involve removal of defective or suspected defective reparable components.
2. That portion of calendar, conditional, periodic, acceptance, and transfer inspections which involves the search for (not repair of) defects, sometimes called the "look phase."
3. Removal of components for check, test, inspect, and service actions.
4. Item removal and replacement for cannibalization.
5. Fix-in-place actions discovered during inspections.
6. Recording manhours accumulated during work stoppage for parts or maintenance.
7. Recording accumulated maintenance manhours at the end of a reporting period for a job not completed.
8. To report assistance from work centers in support of a basic work center.
9. In support of a reparable item processing through an intermediate maintenance activity.

SECRET 10933

Multicopy MAF

This form, provided in four-copy sets, is used when processing a defective or suspected defective reparable component through the intermediate maintenance activity. It is also used to induct a component (including engines) into an intermediate maintenance activity for compliance with technical directives. However, the multicopy MAF is not used for the accomplishment of test, inspect, and service actions. Instead, see 9, under Single Copy MAF.

Each copy of the multicopy MAF is used as follows:

Copy 1—Used for removal/replacement of reparable components from aircraft, engines, or support equipment.

Copy 2—Used to provide status control and suspense information to the Component Control Section of the Supply Support Center for items undergoing processing in the intermediate maintenance activity.

Copy 3—Used to document the action taken by the Intermediate maintenance activity on reparable components. Such actions include a determination that the part was beyond the capability of maintenance (BCM), repaired, checked OK, etc.

Copy 4—Used to provide status control to the Component Control Section of the Supply Support Center and serve as an information copy for all off-station shipment of all material requiring rework.

WORK REQUEST

The NavAir 4710/6 is provided for use as a work request. This request form will be utilized for the following:

1. Requesting check, test, and servicing of items removed from an aircraft or equipment for scheduled maintenance.
2. When requesting work or assistance which is beyond the requesting activity's capability and does not involve repair of aeronautical material (i.e. when the MAF does not apply).
3. To induct components into IMA from Supply for technical directive compliance, updating, and check and test.
4. To induct items into IMA, from an Organizational level maintenance activity, that are not part of an aircraft or support equipment (i.e. pilots personal equipment, oxygen masks, life preservers, etc.) that require check, test, servicing, or minor repair.

The organization requesting check and test will fill out the 4710/6 Work Request in duplicate. In addition to the information required by the 4710/6, the following additional information must be included:

1. Job Control Number or Work Request Number.
2. BUNO/Serial Number of the aircraft/equipment from which the item was removed (if applicable).
3. Type Equipment Code.
4. Nomenclature and Serial Number of items to be checked. Any number of like items may be included on a single 4710/6. The check and test items will be delivered to a production division of the IMA. For further details of the Work Request Form 4710/6 see figure 2-6.

UNSATISFACTORY MATERIAL/
CONDITION REPORT (UR)

The Unsatisfactory Material/Condition Report (UR) is a four-page set, carbon interleafed, snap-out form, and is a supporting document of the Maintenance Data Collection System. The UR is intended to provide a method for the expeditious reporting of special situations and safety conditions. The use of this form provides a direct narrative link between the user and the responsible supporting activity and therefore should be used when prompt corrective action is required and/or amplifying details are necessary beyond those provided by means of routine 3-M documentation.

The purpose of the UR is to provide all activities concerned with aeronautical material with a system for reporting SPECIAL SITUATIONS which require prompt attention and corrective action and insure that the Naval Air Systems Command Headquarters, its field activities, contract administration agencies, supply activities, and industry are promptly appraised of material defects and failures which have a serious impact on operational safety, fleet readiness, and aircraft delivery.

Although the Maintenance Data Collection System provides for reporting of routine defects and failures, the UR provides a system for submittal of specific information concerning failures, material defects, and other critical situations affecting naval aeronautical equipment which require prompt attention and corrective action.

The front page of each UR set contains instructions for the completion of the form. These

10034

Figure 16-4. —Improving the basic circuit.

volts. As a result, the grid of V1 is 203 volts negative with respect to its cathode.

Since the direction of capacitor current is reversed, the plate voltage source will aid the discharge of the capacitor. When a source is connected to a charged capacitor with a polarity that discharges it, the capacitor will completely discharge and recharge to the new voltage all in one long exponential curve. In this case, the curve will have the same amplitude as it would if charged from zero to 503 volts. The resulting slope is as shown in figure 16-4 (A). Of course, the slope due to the more rapid discharge will go through zero earlier if the same RC is used. Therefore a longer RC must be used when grid resistors are returned to a positive voltage than is used when the resistors are returned to ground, for the same duration of output pulse.

SERIES LIMITING RESISTORS. —The use of series limiting resistors in the grid circuits of this multivibrator increases the squareness of the waveshapes. In the circuit shown in figure 16-6, these resistors are R5 and R6. The first half cycle of the plate and grid waveshapes shown is without the grid limiting resistors in the circuit, and the second half cycle is with R5 and R6 in the circuit. Note that the grid does not go positive when resistors are provided. When the other plate becomes more positive most of the voltage change occurs across the grid limiting resistor while only a small fraction of a volt exists between the grid and cathode, provided that the grid limiting resistor is of the order of 500K or more. The plate that is going positive cannot normally rise in voltage any quicker than the coupling capacitor can charge. Therefore in the normal circuit, the plate waveshape resembles the coupling capacitor charging curve. When grid limiting resistors are inserted, each limiting resistor is in series with the low grid to cathode resistance, and with the grid-leak resistor, forming a high resistance circuit for the capacitor to charge through. The circuit is like the trapezoidal sweep generator in that a "jump" voltage will occur across the limiting and grid-leak resistors. The exponential rise will start from there. In the waveshape of this illustration, the jump is about 90 percent of the total amplitude, with only slight rounding of the leading edge of the pulse.

RADAR SWEEP CIRCUITS

The range sweep in a radar set is of paramount importance for the correct presentation of target information. To accomplish this, a sawtooth voltage or current of proper amplitude and slope must be supplied to the indicator's deflection system. This discussion will include a typical range sweep circuit used for generating a linear sawtooth of the proper amplitude and time duration. The same circuit is used to generate the sweep for more than one range, and yet maintain the same physical sweep length on the scope. Since the basic circuits involved in the sweep generator are discussed in chapter 8 of AT 3 & 2, NavPers 10317-C, only its actual operating condition is explained in detail in this chapter.

SWEEP GATE CIRCUIT

The sweep gate circuit consists of a one-shot multivibrator, V6 and V8 (fig. 16-7), a negative grid clamper V7, and two sweep gate amplifiers V26 and V27. (NOTE: V26 and V27 are discussed later in the chapter.) It should be noted that V8 is cut off in static condition by the voltage divider network in its grid circuit and that V6 is conducting. The circuit is triggered by a negative pulse which is applied to the grid of V6. It should be recalled from the discussion

instructions should be read carefully before the form is completed. The spaces should be completed by use of a typewriter or ballpoint pen. If a ballpoint pen is used, care should be exercised to insure that all copies are legible. The back of the form may be used if additional space is required.

Detailed procedures for the preparation, security classification, and mailing of completed UR's are contained in the current NavAir 4700.2 Instruction.

SUPPORT ACTION FORM (SAF)

The separate reporting of support type data is designed so that time expended in the accomplishment of repetitious type tasks that consume many manhours (but do not involve malfunctions, repairs, or condemnation action) may be easily identified, reported, and monitored. Manhours expended in support duties (such as aircraft refueling, engine or tire buildup, parachute packing, etc.) are documented on the Support Action Form (SAF).

The SAF is a standard electric accounting machine (EAM) card which may be either handscribed or prepunched and preprinted, depending upon the desires and requirements of local maintenance managers. In either case, all support action forms are signed by the work center supervisor to indicate that screening has been accomplished. Figure 2-7 illustrates a handscribed support action form.

In order to identify manhours expended in specific categories of support type work, 3-character codes known as support action codes are used. Nine basic categories of support type work and the related code for each are listed on the back of the SAF form together with type maintenance codes.

Support codes may be further broken down within basic categories if deemed appropriate by local command; i.e., 011, 012, etc. In the event such a breakdown is desired, its use is controlled by the maintenance officer and managed by the analysis section. The areas of support work covered by each basic category are defined in detail in an appendix to the

Maintenance and Material Management Manual (3-M Manual).

Support Action Forms are filled out in the following manner:

Type Equipment Code. Enter a 4-character code that identifies the equipment on which support work is being accomplished; i.e., aircraft, engines, ground support equipment, etc. This code is found in appendix H of the 3-M Manual.

Action Organization. If the SAF is not preprinted and prepunched, enter the 3-character code that identifies the organization accomplishing the support action. This is the same alphanumeric organization code that was explained in connection with the Maintenance Action Form.

Work Center Code. This, too, is the same numeric code series that is used with the MAF.

Maintenance Level. If the card is not prepunched and preprinted, enter the 1-character numeric code that identifies the maintenance level of the support action being performed. These codes are provided on the front of the SAF.

Action Date. The action date is the Julian date of the day the support action was completed.

Support Code. Enter the 3-character numeric code that identifies the category of work in which the support action was accomplished. These codes are listed on the back of the SAF.

Type Maintenance Code. This is a 1-character alphabetic code that identifies the type of support maintenance that was accomplished.

Items Processed. Entered here is the number of items processed, or the number of times that the support action identified in the support code block has been accomplished (i.e., 4-aircraft refueled, 3 preflight inspections accomplished, etc.).

Manhours. Enter the total number of manhours (in hours and tenths of hours) spent in the accomplishment of the support action documented on the same line of the card. A maximum of 999.9 manhours may be reported on one line entry.

Local Control. Provided for local use, if desired.

Signature. Enter the signature of the person documenting the support action.

Replenish. If preprinted, prepunched cards are used, enter a checkmark in the REPL block when more cards are needed. The maintenance officer controls and the analysis section coordinates the production, volume, and distribution of preprinted prepunched cards.

The Support Action Form is designed so that documentation may be completed by either the work center supervisor or the individual worker. Additionally, the card provides a multiple entry feature so that several different entries may be made on the same form.

MANHOUR ACCOUNTING

The effective use of available manpower is an important function of maintenance management. Manhour accounting is an important part of the Maintenance Data Collection System. The purpose of collecting manhour data is to provide management with essential information necessary to more efficiently plan and direct the distribution of assigned personnel.

This system is based upon the "exception" principle; that is, only the deviations or exceptions from normal are reported. Through the use of master rosters, electric accounting machine cards, and machine processed reports, the system provides summaries of the hours expended by maintenance personnel during the normal working day or in an overtime status. Basically, the system is designed so that the normal working hours for each person assigned to the maintenance activity are allotted or assigned to work centers by types of labor at the beginning of each reporting period. Exceptions from these normal working hours, or labor types, are reported by use of Manhour Accounting (MHA) Cards. Data processing machines add or subtract the exceptions reported on the MHA Cards from the initial manhour allotment. These exceptions and the working hours allotted at the beginning of the period serve as the basis for the daily and monthly manhour accounting reports mentioned in the foregoing. These reports are forwarded to the maintenance officers and supervisors for validation and utilization. Each supervisor and worker must thoroughly understand the importance of the system, its operation, and the need for continual accuracy. Detailed instructions pertinent to the content and use of manhour accounting reports are contained in the following paragraphs.

At the beginning of each reporting period, generally the first of the calendar month, manhours are assigned to every work center to which personnel are assigned. These manhours are based on an 8-hour work day 5 days

AFCOL 10937

per week for every person assigned. Not included in these "Original Assigned Manhours" are any hours for work on Saturdays, Sundays, or holidays during the month. If every person assigned to the work center could be continuously employed throughout the month during all the time available for work, there would be no need for manhour reporting, as the time would be accounted for on the Maintenance Action Form. Since continuous employment is not possible, each worker must report what he did when he was not working during any period in excess of 20 minutes, or approximately three-tenths of an hour.

To simplify reporting of hours spent in a labor category other than that for which assigned, a group of MHA Cards is provided for every worker assigned. A card is initiated each time a person excepts from normal for a period in excess of three-tenths of an hour and is completed at the end of the exception. The most frequent exceptions requiring the submission of MHA Cards are (1) each time a person is assigned to, or transferred from, a work center or organization, (2) each time a person performs work in other than his regularly assigned labor code, (3) each time a person is absent from his work center for nonmaintenance purposes such as watches, leave, sick, special liberty, etc., and (4) each time a person works overtime during a single work day or on his day off (holiday, Sunday, etc.).

MHA Cards are, for the most part, prepunched and preprinted. However, handscribed cards have a place in the system. A prepunched, preprinted card is illustrated in figure 2-8.

Handscribed MHA Cards are normally used to report (1) newly assigned personnel, (2) temporarily assigned personnel, (3) composite manhours involving more than one person, and (4) whenever prepunched, preprinted cards are not available.

The use of the blocks and spaces on the MHA Card is discussed in the following paragraphs.

Block 1—Organization Code. The organization code is the same 3-character alphanumeric code described for use with the Maintenance Action Form. Use of the code simplifies the identification of the unit to which a person or persons is/are attached or temporarily assigned. For example, AY 1 is the code for RVAH-1, and is much easier and faster to write in than the name of the activity.

Block 2—Work Center Code. The work center code identifies the functional area to which a person is assigned or temporarily assigned. A standard system of work center codes is prescribed. Therefore, a PR assigned to the airframes division at the intermediate level of maintenance anywhere in the world would use

PR.109

Figure 2-8.—Prepunched/preprinted MHA Card.

10938

500 as his work center code. Those PR's attached to the aviators equipment branch at the organizational level of maintenance all use work center code 130.

Block 3—Name and Initials. This block is self-explanatory, except that in the case of composite cards (used for two or more persons) enter the applicable number of men; i.e., "2 men," "4 men," etc.

Block 4—Grade Code. This code is a 3-character numeric or alphanumeric code used to designate the grade and status of the individual being reported on. All military grade codes start with 0 and range upward from 001 (recruit) to 019 (captain/colonel). All civil service codes start with G and correspond to their pay status. For example, a GS-1 code is G01 and the top is G14 for a GS-14. Grade codes C01 through C04 are special civilian codes and are provided for use where necessary as directed by the major command.

Block 5—Labor Code. Labor codes in five major categories are prescribed for use here. Manhour expenditures are charged to the labor code which best describes the type of labor performed or how a worker's time was spent. The five major categories are as follows: Direct Labor (500), Productive Indirect (600), Nonproductive (700), Duty Absence (800), and Nonduty Absence (900). All of these code groups except Direct Labor employ digits other than 00 to more precisely picture what was done. For example, Duty Absence (800) is further divided into Military Duty (810) and Military Training (830).

Block 6—NEC/MOS. In this block is entered the primary Navy Enlisted Classification Code or Marine Corps Military Occupation Specialty Code for newly assigned personnel only. Naval Officer Billet Codes (NOBC) or designators may be used for officers. If desired, a person's rating may be entered in block 6A.

Block 7—Initials. The initials of the work center supervisor are entered here to indicate that screening has been accomplished. Every worker assigned to a work center is responsible for submitting his own cards, except when he is absent at the end of a reporting period. In such cases, the supervisor submits the necessary cards. It is the responsibility of the work center supervisor to see that every card submitted by everyone is correct in every detail.

Block 8—Type of Change. It must be kept in mind that maintenance manhours are not reported on MHA Cards. Whenever the normal routine (which is set up on the electric accounting machines) varies or changes for any of the reasons listed in block 8, a card must be submitted AFTER the change occurs. For instance, after being temporarily assigned or transferred or immediately after working overtime. A check (✓) in a block 8 space is nearly always accompanied by a check in block 9, 10, 11, and/or 12. An exception to this is "Replenishments." A preprinted, prepunched card, checked in the "Replenishments" space, is submitted by the man concerned when the number of preprinted, prepunched cards remaining in his personal stack is less than 10. The data center will forward him a new supply the next day. The relationship of block 8 spaces to blocks 9, 10, 11, and 12 will be discussed in conjunction with the coverage of the latter group of blocks.

Block 9—Transaction Work Center. Block 9 is used in conjunction with the "Temporarily Assigned" and "Temporarily Transferred" categories in block 8. When a man is temporarily transferred to another work center, the change requires the initiation of two cards, because it involves two work centers. At his permanent work center he initiates a card checked "Temporarily Transferred" in block 8, and his temporary work center code is entered in block 9. When he arrives at his temporary work center, he initiates the second card. On this card, "Temporarily Assigned" is checked in block 8, and the code number for his permanent work center is entered in block 9.

Block 10—Date. Block 10 is not filled in until the temporary work assignment is completed. At that time the Julian date is entered in this block, identifying the day the exception was completed.

Block 11—Hours. Upon completion of the exception, the number of hours and tenths of hours involved in the exception are entered here. Space is provided for 999.9 hours to be reported on a single card. When Newly Assigned (block 8) is checked, the number of hours reported is the number of hours of normal working time remaining in the reporting period. If "Temporarily Assigned" is the reason for submitting the card, the total elapsed number of working hours while so assigned is reported. The exception to this is when a temporary assignment extends into the next reporting period. In such cases a temporarily assigned card is submitted at the end of the month with that month's hours reported and, when the exception ends during the next reporting

10939

period, another temporarily assigned card is submitted to report only the number of temporarily assigned hours elapsed in that reporting period.

If "Transferred" (block 8) is the reason for submitting an MHA Card, the number of working hours remaining in the reporting period is reported. It will be recalled that the total number of working hours available for a reporting period for a work center is obtained by multiplying the number of men assigned by 5 days per week and 8 hours per day. When a person is transferred during the reporting period, all the working hours that he would have worked had he remained must be subtracted from the work center's total manhours available. The same reasoning holds true for "Temporarily Assigned" where the number of hours in this category is added to the temporary work center's totals and "Temporarily Assigned" where the number of hours in this category is added to the temporary work center's totals and "Temporarily Transferred" where the number of hours away is also deducted from the permanent work center's totals.

Block 12—Transaction Code. An entry in this block is mandatory if "Labor Code Change" or "Overtime" has been checked in block 8. A checkmark is entered to identify the labor code in which manhours were expended. If the "Other" line is checked, the appropriate subcode promulgated by the analysis section is entered in the space provided. The majority of MHA Cards submitted are "Labor Code Changes."

Rectifying Erroneous Data

In the event that erroneous maintenance data enters the system either (1) through faulty documentation or (2) a mistake appears on the daily manhour accounting listing, it is important that the erroneous information be extracted and the correct information substituted therefor. Such errors in blocks 8 through 12 require that two cards be submitted. One is a "Correction" card which is identical to the erroneous card in every respect (even the error is included), except for a checkmark in the "Correction" space in block 8. Through machine manipulation, the two incorrect cards will cancel one another. The second card, containing the correct information, is submitted in order to get the correct information into the system.

Another type of erroneous information that must be changed is when prepunched, preprinted MHA Cards are incorrect due to name changes, promotions, changes to NEC/MOS, or key punch error. When these occur, a "Revision" card is prepared and submitted. This is accomplished by lining out the incorrect information and writing in the correct information just beneath it and checking the "Revision" space in block 8. Revision cards are limited to changing information appearing in blocks 3, 4, 6, and 6A.

Revision of an incorrect organization code (block 1), work center code (block 2), or labor code (block 5) requires the submission of two cards, neither of which is a "Correction" or "Revision" card. In these cases the first card is a "Transferred" card that contains the erroneous entry in block 1, 2, and 5. This removes the previously recorded number of hours from the incorrect account. The second card contains the correct entry in block 1, 2, or 5, as the case may be, and is checkmarked in the "Newly Assigned" space in block 8. This card assigns the hours involved to the correct organization, work center, or proper labor code.

NATIONAL BUREAU OF STANDARDS-1963-A

CHAPTER 3

PARACHUTE FAMILIARIZATION

In 1495, shortly after Columbus discovered America, another great Italian, Leonardo da Vinci, designed the first parachute. This was a huge pyramid of cloth, but a functional parachute was not actually made and used until more than a century later. The word "parachute" is derived from the Italian word "parare," meaning to protect or shield from, and from the French word "chute," meaning a fall or quick descent—literally, "to protect from a fall".

Fouste Veranzio, also an Italian, is given credit for the first parachute jump. He made this jump in 1617 from a tower in Venice, using a parachute made of a square wooden frame, covered with canvas. Since man had no use for a lifesaving device of this nature, parachutes were considered novelties or items of amusement, and interest in them gradually dwindled. It was not until the invention of the first aerial balloon than interest in the parachute was renewed.

In 1783, the Montgolfier brothers invented a balloon which would stay aloft. This balloon was kept in the air by burning bundles of straw beneath the bag to make the necessary supply of hot air. If the fabric should catch fire, the flight was abruptly ended. This meant that men who went up on such flights had to have a means of escape and descent. This necessity for a lifesaving device removed the parachute from the list of novelties.

In 1808, Andre Kuparento, a Polish balloonist, became the first man to leap to safety from a flaming bag of hot air, using a parachute. The need for a foolproof parachute, however, did not become sufficiently acute to stimulate a great deal of inventive effort until nearly 100 years later.

Then, with the coming of the air age in 1903, when the Wright brothers made their spectacular flight at Kitty Hawk, North Carolina, there came also an era of experimentation with parachutes designed especially for the new type of aircraft.

Captain Albert Berry is given credit for being the first American military man to successfully jump from an airplane using a parachute. This jump was made in 1912. His parachute was packed in a coneshaped metal cylinder with a trapeze bar serving as a harness, and the weight of his body pulled the canopy from the container. Many others using makeshift or experimental parachutes made descents before World War I, but parachutes still were not considered as essential equipment for military aviators. The resultant mortality rate among pilots on active duty at the front during the war was very high. This, together with the fact that the lives of 800 balloonist observers and artillery fire directors were saved by parachutes, pointed out a desperate need for a foolproof, lifesaving device. The next logical step then, was to improve parachute reliability and make them mandatory for military aircraft.

With World War II, when the number of naval aircraft was increased tenfold, the parachute became more and more important and its improvement became an important objective of the Navy. Pursuing this objective led to the development of the Naval Aerospace Recovery Facility at El Centro, California.

This facility must test and approve any change to the parachute and/or components, and is responsible for the design and testing of many items now in use.

The Naval Aerospace Recovery Facility, along with the Aerospace Crew Equipment Department at Philadelphia, Pennsylvania, enables personal survival equipment development to keep abreast of the design and development of newer and faster aircraft.

PRINCIPLES OF OPERATION

A parachute is made like a giant umbrella and protects a falling body from severe injury or damage in landing by offering a large air-

158

10921

resisting surface. In each successful parachute descent the same action takes place—the ripcord is pulled, the pilot chute emerges from the pack, and pulls the main canopy out. The canopy fills with air and lowers the body slowly to the ground. This series of events is illustrated in figures 3-1 through 3-7.

PR.110

Figure 3-1.—Exerting a pull of 27 pounds (maximum) on the ripcord releases the ripcord pins from the locking cones. The flaps of the pack are then drawn back by spring-opening bands.

PR.111

Figure 3-2.—The pilot chute springs beyond the negative pressure area immediately above the falling body. This results in its getting a better "bite" on the surrounding air, thus speeding the opening of the canopy.

PR.112

Figure 3-3.—Canopy completely extended. Suspension lines almost completely out of pack.

DESIGN AND CONSTRUCTION

A parachute consists of five major parts: the pilot chute, the canopy, the suspension lines, the pack, and the harness. The pilot chute is a small parachute attached to the top of the main canopy. Its purpose is to retard the main canopy while the weight of the falling body withdraws the suspension lines and inflates the canopy. The canopy is a large area of cloth which slows the descent of the falling body. The suspension lines are strong lines which join the canopy to the harness. The pack is a nylon assembly which encloses the pilot chute, canopy, and suspension lines. The harness is an arrangement of nylon webbing and metal fittings. It is designed to hold the canopy securely to the jumper and provide a seat or sling during descent.

TYPES OF PARACHUTES

There are several basic types of parachutes now in service use by the Navy. Among these are the Navy chest type (NC), the Navy seat type (NS), and the Navy back type (NB). All Navy parachutes are placed in one or the other of these categories. An oversize harness may be used with the NS type parachute; therefore, the letter "R" indicating regular size harness, or the letter "O" indicating an oversize harness, is also included after the model number as a part of the letter designation; i.e., NS-3R.

NAVY CHEST TYPE PARACHUTE

The Navy chest type is attached to the harness with quick connector hardware and is worn on the chest. (See fig. 3-8.) It was designed for use in aircraft where duties of the pilot and

PR.113
Figure 3-4.—Canopy filling with air. Body assuming upright position.

PR.114
Figure 3-5.—Canopy completely open. Opening shock felt.

crewmen require them to have freedom of movement in various sections of the aircraft. When the chest type parachute is used, the harness must be worn at all times during flight.

The pack is usually stored in a spot near the individual's flight station or bailout station, allowing maximum efficiency of the crewman and still providing a high degree of safety. This accessibility of the pack allows quick attachment of the parachute before bailing out.

10943

Figure 16-5.—Effect of returning grid to B plus.

on the timer block diagram that the sweep gate circuit is triggered by a negative pulse from either the master trigger output on normal operation, or the variable delay circuit on time delay operation.

The negative input trigger pulse drives V6 toward cutoff, causing a rise in its plate voltage and a drop in its cathode voltage. This plate voltage rise is coupled to the grid of V8, driving V8 into conduction. The resulting drop in plate voltage is coupled back to the grid of V6 as in any one-shot multivibrator. However, the negative grid clamper does not permit the grid of V6 to be driven below an approximate negative 23 volts.

The action of V7 and the sweep shutoff circuit (fig. 16-8) controls the duration of the output pulses from the sweep gate circuit. (NOTE: The output from the sweep gate determines range sweep time which is discussed later in this chapter.)

The outputs of the sweep gate circuit are as follows:

1. A negative square wave (generated by conduction of V8 through R29 and capacitively coupled to the grid of V6) from the grid of V6 which is fed to the grid of sweep gate amplifier V27.

2. A negative square wave from the cathode of V6 which is used to trigger the compensating gate circuit.

PR.115
Figure 3-6.—Steady rate of descent established. Pilot chute resting on canopy.

PR.116
Figure 3-7.—Parachute deflating as body touches ground.

To be completely effective, it is necessary that every person using a chest type parachute be properly trained in its use. It is obvious that each person aboard an aircraft should be continuously aware of the exact location of his pack at all times.

NAVY SEAT TYPE PARACHUTE

The seat type parachute (fig. 3-9) is the oldest type still in service use. It is designed to be worn as a seat for the wearer, and when in use, fits in the bucket section of the aircraft seat.

It was designated the SS (Standard Seat) when first used in 1924. It continued in use with the same designation and very little change to its design until well into the 1940's.

World War II created a necessity for different designs in parachutes to fit the requirements of newer types of aircraft. This led to the design of the Quick Attachable Seat (QAS) parachute. This parachute was designed to be left in the seat of the aircraft and quickly attached to the pilot's harness. This would help him in getting in and out of the aircraft as well as speed the launching of aircraft.

A later development of this parachute was the Quick-Fit Seat (QFS). This one could also be left in the cockpit of the aircraft, but the harness was permanently attached to the parachute and could be quickly adjusted by the wearer.

10944

PR.117

Figure 3-8.—Navy chest type parachute.

In 1948 all parachutes were redesignated and given their current designations. It was then that the QFS became the NS.

NAVY BACK TYPE PARACHUTE (NB)

The Navy back type parachute is worn on the back, as shown in figure 3-10. This model is

PR.118

Figure 3-9.—Navy seat type parachute.

10945

PR.119

Figure 3-10.—Navy back type parachute (NB) with LR-1 liferaft attached.

ideally suited for use with jet-powered aircraft, the ejection seat, and its automatic devices.

Parachutes of this type are the NB-5, NB-7, NB-7E, NB-8, NB-9, NB-10, and NB-11.

The NB-5, NB-7, NB-7E, NB-9, NB-10 and NB-11 are designed to be used with an integrated torso suit harness as part of the ejection seat escape system.

MARTIN-BAKER PARACHUTE (MBEU)

Another type of integrated parachute designed for use with ejection seats is the Martin-Baker. This parachute has a 24-foot diameter canopy and when configured with the Martin-Baker ejection seat they combine to form the Martin-Baker Escape Unit. The MBEU 622PA parachute assembly has the canopy packed in a rigid, wedge type container. The MBEU 4150PA parachute assembly has the canopy packed in a hard-shell, horseshoe type container. Both the MBEU 4002PA and the MBEU 4004PA parachute are packed in a soft, horseshoe type container; all are specially designed to provide the proper ejection posture or attitude by means of the shoulder and takeup mechanism.

TRAINING TYPE PARACHUTE ASSEMBLY

For all practical purposes the training assembly may be considered as a standard back pack parachute with a chest pack attached to the same harness. Naval Air Systems Command regulations, like those of the Federal Aviation Administration require that two packs be worn when making training or demonstration parachute jumps. The training assemblies are designated the NT5-R or NT5-O, depending on whether the flat circular canopy contained in the back pack is a 28-foot (regular) or a 35-foot (oversize) one.

The training assembly is rarely used in the Navy except at the Aircrew Survival Equipmentman School, Lakehurst, New Jersey. In order for naval personnel to make a premeditated parachute jump at other than this activity, it is necessary to pass a rigid physical examination and to have obtained, through the chain of command, the permission of the Chief of Naval Operations.

NES-8 PARACHUTE

The NES-8A and NES-8B parachute assemblies are recent developments, designed for use

10946

with the Navy Ejection Seat. The NES-8A assembly includes a multicolored, 29.7-foot diameter, ringsail canopy with 24 gores. The NES-8B includes a 28-foot diameter canopy with PDVL. The canopy is packed in a hardshell, horseshoe type container. The assembly is installed in the ejection seat and designed for use with the integrated torso suit harness. The survival kit is also connected to the integrated torso suit by means of quick-release fittings.

LW-3B PARACHUTE

The LW-3B parachute assembly is used with an integrated torso suit harness as part of the ejection seat escape system. The assembly is mounted on the back of the ejection seat on the left side for the LW-3B-1 and on the right side for the LW-3B-2.

The LW-3B assembly includes a 28-foot diameter, flat, nylon canopy with 28 gores. The canopy is packed in a metal-based fabric container.

HIGH ALTITUDE LOW OPENING (HALO) PARACHUTE ASSEMBLY

The high altitude low opening parachute assembly is a back type parachute designed for high altitude free-fall and low opening. The HALO assembly includes a 35-foot diameter, parabolic, nylon canopy with 30 gores. The canopy is packed in a container and secured to the aircrewman's back by means of a harness assembly.

The assembly also includes a parachutist's kit and a chest type reserve parachute.

The HALO parachute assembly is used primarily for premeditated jumps over designated areas where pinpoint landings are necessary. Free-fall parachuting allows greater maneuverability and landing accuracy.

T-10 PARACHUTE ASSEMBLY

The T-10 parachute is a back type parachute designed for static line operation only. The assembly includes a 35-foot diameter, parabolic, nylon canopy with 30 gores. The T-10 parachute assembly is used by paratroopers for premeditated jumps over a designated area.

COMPONENTS OF PARACHUTES

The design and construction of a parachute and its components are based on the old idea that a chain is only as strong as its weakest link. Every link from the jumper to the canopy must carry its share of the maximum load applied during the opening shock.

The five major parts of a standard service parachute, starting at the top and working down, are the pilot chute, main canopy, suspension lines, harness, and pack. Figure 3-11 illustrates these five major parts.

PR.120

Figure 3-11. —The five major parts of a parachute.

PR.121

Figure 3-12.—The vane type pilot chute.

PILOT CHUTE

The vane type pilot chute is used on all Navy parachutes except the Martin-Baker parachute. Figure 3-12 shows the nomenclature or names of parts and materials that make up a pilot chute. A thorough knowledge of this nomenclature will prove invaluable in your future work with parachutes.

CANOPIES

The size and shape of the parachute canopy have been controversial subjects since da Vinci envisioned a pyramid of cloth as being a safe way of falling through the air. After experimentation with many different canopies over the years, two shapes have emerged as acceptable. One is the standard flat design which has remained virtually unchanged for the past 30 years. The second is a new idea in construction, but still follows the basic shape pattern. This latter canopy type is known as the 26-foot 22-gore conical canopy. This canopy is used with the NB-5 and NB-6 parachute assemblies. The "conical" reference comes from the fact that the peak of the canopy is conical in construction. In descent the canopy presents a slightly raised shape at the apex, but fails to radically change the basic appearance so familiar to the service.

Standard Flat Type

The 28-foot ripstop nylon canopy is the old standard size used on all Navy parachutes. The

10948

parachute canopy is described as a polygon, having 28 sides, a diameter of 28 feet plus or minus 1 inch, and 28 gores of 4 sections each.

The 28-foot canopy contains approximately 796 square feet of nylon cloth plus 2,400 yards of nylon thread. The sewing on a parachute varies from 8 to 11 stitches per inch. The parachute contains approximately one-half million stitches with a canopy area as great or greater than many 2-bedroom homes.

The suspension lines run continuously from the connector link on one side of the 28-foot canopy to the connector link on the other side as illustrated in figures 3-13 and 3-14.

The following additional items concerning the standard flat canopy should be noted:

1. Each gore is composed of four sections identified by the letters A, B, C, and D, starting with the bottom section.

2. Diagonal seams run parallel to the warp thread in the cloth, the warp changing direction with each gore. The sections are cut at a 45-degree angle to the centerline of the gore. This is called BIAS CONSTRUCTION and provides the maximum strength and elasticity.

3. The radial and diagonal seams are double lapped for security.

4. The suspension lines are enclosed in the channel produced by stitching the radial seams.

5. The vent acts as a relief valve and relieves the high internal pressure within the parachute at the instant of opening. Without this vent, an opening at high speed could result in a dangerous rupture of the canopy.

6. The skirt and vent hems are reinforced with 1-inch nylon webbing to aid in preventing tears from completely separating the canopy.

7. The following is stenciled on the top center gore (section A of gore number 28) in letters 1/2 inch high and approximately 12 inches from the bottom of the canopy:

NAVAIRFAC
ORDER NO.
DATE OF MANUFACTURE AND SERIAL NO.
MANUFACTURER'S NAME OR TRADE MARK

Stenciled on the diametrically opposite gore (section A of gore number 14) is found the following:

PR.122

Figure 3-13.—The 28-foot ripstop canopy.

109491

PR.124

Figure 3-15.—Conical canopy, 26-foot, 22-gore.

6. The rate of descent has been sacrificed to a certain degree in order to increase the strength and stability of the parachute.

SUSPENSION LINES

The suspension lines form a net or skeleton for the canopy and absorb much of the shock load. They must therefore be placed under a 20-pound tension, marked, and cut as a group to assure equal distribution of the shock load. The 28 suspension lines counted at the links are actually 14 lines, 75 feet 4 inches in length. These lines run continuously from link to link; that is, each line is secured to a connector link on one side of the canopy, runs up and over the

10951

canopy, and down to a link on the opposite side.

Type III nylon suspension line is used on all main canopies and vane type pilot chutes. This line consists of a loosely woven outer covering called a sleeve, and several strong inner cords called the core. This core provides the greater portion of the strength of the suspension line.

Figure 3-16 illustrates the arrangement of the suspension lines on both the 28-foot and the 26-foot canopies. On the 28-foot canopy the lines are arranged in four groups of 7 lines each, while on the 26-foot canopy they are arranged in two groups of 5 and 2 of 6 lines each.

The suspension lines are attached to the connector links by tying a clove hitch, a half-hitch, and completing the attachment with 2 inches of zigzag stitching. This attachment is shown in figure 3-17.

To prevent the canopy on the 28-foot parachute from slipping along the suspension lines, each line is anchored by zigzag stitching at several points to the radial seams through which it passes. One-half inch of slack is allowed in the vicinity of the skirt between the zigzag sewing points to relieve the strain during opening shock.

PARACHUTE HARNESS

Parachute harnesses are designed to secure the parachute to the wearer and provide support during opening shock and descent. The harnesses currently being used by the Navy are the quick fit (so called because of the ease and speed with which they may be adjusted by the wearer) and the integrated torso harness.

The integrated torso harness combines parachute harness, lap belt, and shoulder harness into one integrated garment which improves comfort, mobility, and retention, and is easier to don and remove. It also reduces the number of exposed straps and overall bulk and weight. This harness is discussed in detail in chapter 15.

The parts of the parachute harness which take the load during a descent are nylon webbing of a

PR.125

Figure 3-16.—Suspension line arrangement.

10952

PR.126

Figure 3-17.—Method of attaching suspension lines at the link.

PR.127

Figure 3-18.—Back type quick-fit parachute harness.

soft weave, conforming to Specification MIL-W-4088D, and metal fittings of alloy steel which are proof loaded in accordance with applicable standard drawings.

The standard quick-fit harness is made in three configurations—seat type, back type, and chest type. The seat and back types are the same in design construction except that the seat type requires lift webs of greater length to compensate for difference in the location of the packs. The main parts of these harnesses are the combined main suspension sling and lift webs, leg straps, horizontal backstrap, diagonal backstrap (or cross shoulder strap), and chest straps. (See fig. 3-18.)

The principal difference between the chest type and the seat or back type harness is that on the NC-3 harness the lift webs separate from the main suspension sling at a point near the chest on each side of the body. This is accomplished by the incorporation of two D-rings in the harness sling and two connector snaps in a separate lift web assembly.

The lift web assembly consists of two equal length straps each laced through the webbing slot of a connector snap. The connector snap is located at the middle of each strap, which is folded back and sewn together just above the snap. The loose ends of each are sewn to individual links connecting to the canopy. Two connector snaps are joined by a cross-connector strap which prevents collapse of the

Figure 16-6. —Using series limiting resistors.

3. A positive square wave from the cathode of V8 which is used as a gating voltage. The relationship of the output waveforms to the master timing pulse is shown by waveforms (1), (2), and (3) of the figure 16-9.

The sweep gate amplifier V27 and sweep gate output V26 circuits are discussed later in this chapter with the intensity gate circuit.

SWEEP CLAMP, SHUTOFF, CHARGING CLAMP, AND BOOTSTRAP AMPLIFIER

Before considering the overall operation of the circuit illustrated in figure 16-8, the functions it performs are discussed. The circuit may be divided into three stages with each stage performing a separate function.

The first stage consists of the RC network composed of C18 to C21, R37, R38, R39, and the two diodes V10A and V10B. The RC network is used to generate a sawtooth waveform for use as a range sweep voltage. V10A and V10B function to clamp the upper plates of the sweep capacitors (C18 through C21) at near ground and provide a means of eliminating the clamping action during sweep time.

The stage V9 controls the amplitude of the sawtooth voltage waveform. It also generates a pulse which cuts off the sweep gate output voltage when the sawtooth voltage reaches the desired amplitude.

It should be remembered that at any instant the charge on a capacitor depends on the RC time of the network and the applied voltage. For the fixed ranges (all ranges except 5-60 miles), range is controlled by switching in various size capacitors and the applied voltage is held at a positive 150 volts. In the variable range (5-60) mode of operation, the applied voltage is varied by the variable range control R606.

Referring to figures 16-7 and 16-8 note that without an input signal, current (electron flow) will flow from ground up through R28 to the cathode of V10A, from cathode to plate of V10A, through R37 and R39 to cathode of V10B, from cathode to plate of V10B, and to pin 8 of relay K6. Pin 8 of K6 is connected to a positive 150 volts through pin 7 when the equipment is operating on a fixed range. When operating on a variable range, pin 8 is connected to the variable range control R606 which forms a voltage divider network between ground and a positive 150 volts.

The path from K6 through R34 to the top of R35 has negligible effect because of its high resistance. The static current maintains the plate of V10A at a relatively low potential which also determines the static voltage across capacitors C18 thru C21. (The relative size of R28 to R37 plus R39 clamps the plate of V10A slightly above ground.) The sweep cutoff tube V9 is biased beyond cutoff by a positive potential applied to the voltage divider network in its cathode circuit. The cathode potential of V9 is important since it determines sweep amplitube which indirectly controls sweep time.

Now consider the operation of the circuit when a signal is applied. (For the following discussion refer to waveforms illustrated in figure 16-9.) A positive square wave taken from the cathode of V8 is applied to the cathode of V10A. It should be remembered that this square wave is generated by the sweep gate multivibrator. With the cathode of V10A now more positive than its plate, V10A is effectively removed from the circuit. The sweep charging capacitors (C18 thru C21) may now charge at an RC rate as determined by the RC network being used. As the sweep capacitors charge toward 150 volts (assume fixed range operation), the grid of V9 will also rise

canopy in the event that only one snap is attached to the harness D-ring. The lift web is tacked to the pack with cord which breaks when the canopy inflates and allows the pack to break away. The chest type harness and the lift web assembly are illustrated in figure 3-19.

The date of manufacture (month and year) should be stamped with black washproof ink,

PR.128

Figure 3-19.—Chest type harness and lift web assembly.

10954

TT-I-542, in letters 1/2 inch high on either the inside of the horizontal backstrap or on the inside of the sling. All exposed ends of webbing should be seared to prevent fraying; and unless otherwise specified, all machine stitching is to be 6-cord sage green nylon thread with not less than 4 nor more than 6 stitches per inch. Ends of all stitching should be backstitiched a distance of not less than 1/2 inch.

PARACHUTE CONTAINER

The parachute container is designed to house and protect the pilot chute, main canopy, and suspension lines. It is made of type III nylon fabric, conforming to Specification MIL-C-7219B, amendment 1. The outside covering of the NC-3 container is cut in one piece on the bias. This is necessary to provide adequate elasticity for the pack. The machine stitching on the container is made with type E nylon thread, 6 to 8 stitches to the inch.

Figure 3-20 through 3-22 illustrate the three general types of containers used with the standard service type parachutes.

Additional information on the material used in this work may be found in NavAir and Air Force publications, along with Military and Federal Specifications. Frequent reference to these publications is necessary to keep your technical knowledge up to date.

RIPCORDS

The ripcord is a manual releasing device, used to release the canopy from the container. It consists of locking pins securely attached to a length of 3/32-inch diameter corrosion-resistant steel cable. The ripcord handles are made of steel tubing in the shape of a cloverleaf or a trapezoid, and are attached by passing the cable through a small hole drilled in the grip and then swaging a retaining ball or clamping a small sleeve onto the loose end of the cable. The pins are swaged in place and tested to withstand a pull of 300 pounds.

An extensible ripcord is shown in figure 3-23. This type is used with the seat type parachute and makes changing to or from the pararaft easier by eliminating the need of changing to longer or shorter ripcords.

RIPCORD HOUSING

The ripcord housing consists of a flexible steel tube affixed to the parachute container at one end and to the main sling on the left side of the harness at the other. It is provided to house the ripcord cable and prevent accidental opening of the parachute. The housing is secured to the harness and container in such a manner as to permit the parachute assembly to be improperly lifted by the housing without withdrawing the ripcord locking pins from the locking cones on the parachute container.

RIPCORD GRIP POCKET

The ripcord grip pocket is made of type III nylon fabric conforming to Specification MIL-C-7219B, amendment 1. It is designed to retain the ripcord grip under normal circumstances and still provide ease in removal when the ripcord is properly pulled.

SEAT CUSHIONS AND BACK PADS

Some of the older type parachutes still use seat cushions and back pads. These cushions and pads are made of foam rubber covered with canvas and are designed to provide comfort to the wearer when attached properly between the parachute harness and the wearer.

As shown in figure 3-24, the cushion is a part of the survival kit when used with the NB-7E in the RA5C type aircraft. This cusion is made of a sponge type polyurethane pad and is bonded to the contoured surface on top of the upper half of the container. The parachute and upper half of the container are secured together by zipper flaps at the lower end of the parachute and at the aft end of the container upper half.

The NB-9 parachute, as used in the A-4 (A4D) type aircraft, uses the seat pan assembly as a cushion. This assembly serves both as a cushion for the pilot and a container for the emergency bailout oxygen supply cylinder. As illustrated in figure 3-25, the seat pan consists of a metal pan, shock pad, foam comfort pad, 28-inch U-shaped oxygen cylinder, and a cover which is zippered over the complete assembly. The pararaft kit is attached to the bottom of the seat pan and both are fitted into the seat bucket.

10959

PR. 134

Figure 3-25. —Seat pan assembly.

RIGID SEAT SURVIVAL KIT (RSSK)

The rigid seat survival kit is designed for use with an ejection seat and functions as a seat cushion for the crew member as well as a container for an emergency oxygen supply, liferaft, and survival equipment. (See fig. 3-26.)

The survival kit consists of an interconnected lid, lower container, and a cushion which forms a seat for the crewman. Mounted inside the lid is an oxygen system for emergency use. An oxygen/communication hose, installed on the aft left hand side of the lid, provides connection between both the emergency and normal aircraft oxygen supplies and the crewman. The longer hose of the oxygen/communication hose connects to the aircraft system and the short hose connects to the crewman's personal leads. Both hoses incorporate quick disconnect features.

The lower container provides space for the LR-1 liferaft and and an equipment bag which contains survival equipment.

Two adjustable straps, permanently installed on the kit lid, provide attachment of the survival kit to the crewman's parachute torso suit harness via two quick disconnect releases. An emergency oxygen actuator is mounted on the front of the lid.

PR. 135
Figure 3-26. —Rigid Seat Survival Kit RSSK-8A.

When the green ring, incorporated in the emergency actuator, is pulled, the emergency oxygen supply flows to the crewman. This actuator is automatically operated during ejection from the aircraft by a lanyard connected between the actuator and the aircraft structure. When the yellow handle, located on the forward right hand side of the survival kit, is stripped from the kit by the crewman, following airborne emergency egress from the aircraft, the lower container separates from the lid. The lid remains attached to the crewman by the parachute side straps; the container and inflated liferaft are deployed on a dropline connected to the lid.

PARACHUTE HARNESS HARDWARE

Parachute harness fittings (hardware) are small metal devices usually made of cadmium or chrome-plated steel. They are designed to join the parachute pack and harness and to afford easy and rapid adjustment of the harness to the wearer.

The many types of parachute harness fittings include adapters, snaps, D-rings, V-rings, connector links, and rocket jet canopy release fittings. Some of the more common types of these fittings and their tensile strengths are illustrated in figures 3-27 and 3-28.

ADAPTERS

Two types of adapters are used with a regular quick-fit type harness. They are the regular harness adapter and the friction adapter. The harness adjuster adapter is used to adjust the harness to the wearer and the quick-fit adapter has a grip slide bar which facilitates quick adjustment of the harness by the wearer.

SNAPS

There are several types of snaps in use with parachutes. They are the plain harness snap, the quick-fit snap, and the quick connector snap. The harness snap is a plain hook-shaped, spring-actuated guard, which snaps over a V-ring to secure two parts of the harness together. The quick-fit snap is similar except that it has a grip slide bar. The quick connector snap is similar to the harness snap and is used as a means to quickly attach the Navy chest type parachute to the two D-rings on the Navy chest type harness.

CONNECTOR LINKS

Connector links are fittings designed to join the parachute to the harness. The suspension lines are attached to one side and the harness to the other.

Rocket Jet and Koch Release

Integrated torso harnesses are equipped with two connector links (D-rings) which attach to the rocket release fittings on the lap belts of the integrated parachute. In addition, two Koch parachute release fittings are attached to each side of the upper chest of the torso harness and the riser assembly of the integrated parachute. Release fittings are manufactured in two parts—male and female. The male portion is attached to the torso suit, while the female portion is attached to the riser assembly of the parachute. Figure 3-29 shows the Rocket Jet and Koch parachute release, while figure 3-30 shows the attachment of the fittings to the integrated torso harness.

Inspection and Testing Rocket Jet Hardware

Inspection and testing of the release must be performed concurrently with the parachute repack. Visually inspect the release for cracks

10961

Figure 3-27.—Parachute harness hardware.

and structural damage. Operational testing must be performed by personnel wearing a torso suit harness. With the parachute riser and/or lap belt fittings placed properly over the shoulder and thighs and with the webbing tensioned to approximate operational loading, each fitting must be locked and unlocked 25 times without binding or failure. The release operation must be accomplished by fully depressing both lock buttons and pushing the collar fully against the stop pins. When the buttons are released and the collar pulled downward in the locking operation the collar should close by spring action the last 1/8 inch of travel. During the cycling

10962

PR.137

Figure 3-28.—Parachute harness hardware—Continued.

operation, there should be no binding or hang up. Attempt to operate the collar by depressing one lock button at a time. The collar should stay locked when either lock button is depressed separately. Fittings which fail to meet either of these operations must be removed and replaced.

If it appears that foreign particles inside the release are affecting operation, clean with compressed air with a maximum pressure of

10963

10963

Figure 16-7.—Sweep gate circuit.

at the same rate. When the grid voltage rises sufficiently to overcome its cathode bias, V9 will conduct, producing a negative-going pulse of sufficient amplitude to cut off V8. Since the conduction of V8 provided the voltage source which cut off the clamping circuit (V10A), the circuit will not return to its static condition.

The time required for V9 to conduct was determined by its static cathode potential and the RC network being used to generate the sawtooth voltage waveform (assuming a constant sweep amplitude). Therefore sweep time is controlled by varying the values of resistance and capacitance in the charging circuit on all fixed ranges.

The relationship of the MTP to the waveforms of the range sweep generating circuits is shown in figure 16-9. Waveform (3) is the positive square wave which disables the clamper V10A. It should be noted that waveforms (4) is a sawtooth superimposed on a low amplitude square wave. The square wave portion, called a jump voltage, is developed across R38 when V10A is cut off. Waveform (5) should be studied noting that when the sawtooth voltage reaches cutoff, waveforms (2), (3), and (4) are also terminated.

The output of the sweep charging circuit, a positive sawtooth on a pedestal, taken from the plate of V10A is directly coupled to the grid of the sweep amplifier V12. (NOTE: The operation of V11 has been omitted purposely at this time; however, it is discussed later in this chapter.) This output waveform is shown as waveform (1) of figure 16-10.

Sweep adjustments are provided to allow the technician a means of compensating for any slight variations in circuit parts. R36, located in the cathode V9, is a screwdriver adjustment for setting the sweep amplitude. R39 is a similar adjustment, but it permits a fine adjustment of the sweep slope or sweep time.

SWEEP AMPLIFIER CIRCUITS

You should now be familiar with how the sawtooth sweep is generated and how it is used as

1094

PR.138

Figure 3-29.—Rocket Jet and Koch canopy release.

50 psi. Clean the exterior surface of the release using a cloth dampened with an approved cleaning solvent. Prevent the cleaning solvent from contacting interior working parts, such as springs and pins. NOTE: Do not lubricate the release.

10964

Figure 3-30.—Rocket Jet and Koch fittings on integrated harness.

10965

CHAPTER 4

PARACHUTE LOFT ARRANGEMENT AND PARACHUTE INSPECTION

PARACHUTE LOFTS

The parachute loft is the work area designated for the inspection, maintenance, repair and packing of parachute assemblies, systems, and components. The design and style of parachute lofts ashore and afloat will vary in size and maintenance capabilities, depending upon the space available, loft equipment, and the activity's basic mission. The three general types of parachute lofts currently in use are the shore-based parachute loft, the shipboard parachute loft, and the portable advanced-based parachute loft.

The shore-based parachute loft is designed and equipped to perform repairs generally required of the higher levels of maintenance. The shipboard parachute loft is designed and equipped to perform repairs at the lowest maintenance level possible. The portable advanced-base parachute loft should be equipped to perform limited repairs. All parachute lofts must be manned by qualified Aircrew Survival Equipmentmen.

Proper utilization of the limited working space alloted to the parachute loft is a primary concern and responsibility of the branch supervisor. In order to accomplish the vast amount of work that flows through the parachute loft, everyone concerned must cooperate by adhering to a well-planned work schedule.

PARACHUTE PACKING SECTION

The parachute packing section is devoted to packing and inspection of parachutes. Parachute packing tables naturally occupy the greatest area of the loft. Thorough consideration should be given to the number of tables that can be successfully utilized, allowing ample working space around the tables. Packing tables must be of sufficient length to allow laying out the complete parachute assembly for inspection and packing. The recommended dimensions are 45 feet by 36 inches by 36 inches.

A cutaway packing table is the least tiring to use, as the packers do not have to stretch across its full width during the closing and finishing of the packing.

Workload

The number of air groups, the types of parachutes, the number of parachutes assigned each, and the loft equipment will have to be taken into consideration in order to determine the number of tables necessary to adequately carry out the prescribed packing schedule. There are many factors that determine the workload of a parachute loft.

Packing operations should not be interrupted and the area where the tables are located should be kept free of traffic. Spacing the tables at least 3 feet apart and parallel to each other provides the best arrangement.

Lighting the parachute loft is very important. It takes good eyes and good lighting to find stitching irregularities and ruptures in glossy white material. Fluorescent lighting has been found to be best, as it gives a flat light bright enough for inspecting, packing, and sewing machine work. However, parachutes should not be exposed to fluorescent lights closer than 5 feet for long periods of time.

Parachute inspection tables have glass tops and are illuminated by fluorescent lighting from beneath the table top. The inspection table should be long enough to inspect an entire gore at one time, be smooth and free of slivers and burrs, and radiate minimum heat from the lighting source.

Do not leave parachutes on lighted tables longer than required for an inspection. Excessive exposure to artificial lighting is harmful to nylon parachute materials.

10966

ENVIRONMENTAL REQUIREMENTS

Regulated temperature and humidity conditions must be maintained in the parachute loft wherever possible; advanced-based and temporary facilities are the exceptions. The temperature and humidity in the parachute loft must be maintained within specified limits, ideal conditions in the packing section being a temperature of 75°F and a relative humity of 60 percent. The loft must be kept free of dust and dampness and be well ventilated.

DRY LOCKER

The dry locker, or drying tower as it is sometimes called, is used to condition parachutes which are subjected to excessive moisture. The dry locker must contain controlled environmental conditions. The height of the dry locker should be sufficient to permit the parachute to hang full length without touching the walls, the deck, or other parachutes. To suspend freely, a 28-foot parachute requires a height of approximately 45 feet; and for adequate drying, the hoisting lines should be a minimum of 2 feet apart, and at least 12 inches from the bulkhead.

For adequate lighting, the flush type, low heat, incandescent light fixtures are recommended; the dry locker should be devoid of windows or skylights.

A dry locker is shown in figure 4-1, which illustrates one of the many possible floor plans of a typical parachute loft.

WET LOCKER

The wet locker is used for drying parachutes after washing. It must be a separate compartment from the dry locker, and must be provided with dehumidification and deck water drains. Other construction features of the wet locker are similar to those of the dry locker requirements.

WASHROOM

The washroom is used for washing parachutes. It should contain a large tub or vat of sufficient size to allow complete submersion of the parachute assembly. Hoist lines should be provided over the tub to simplify handling of the parachute.

STORAGE AREA

Bins, shelves, and cupboards must be provided in the parachute loft to accommodate packed or unpacked parachutes and various other components. The shelving should be designed to facilitate storage of parachutes at least 4 inches from the walls and 12 inches from the deck. The storage area must be well ventilated and free of dust and other contaminates.

SEWING SECTION

The sewing section of the parachute loft must be equipped with sewing machines, cutting tables, fabric racks, and a suitable locker facility.

The cutting table should be from 30 to 33 inches high, so that the PR may comfortably perform any cutting operation. The table should be at least 54 inches wide to handle the most frequently used widths of materials. The table length will depend upon the available area and workloads.

The fabric rack should be located adjacent to the cutting table, as it is used for the purpose of stowing fabric materials in the sewing section; A fabric rack should be designed and constructed of considerable strength in order to accommodate large heavy rolls of material. The rack may or may not be portable.

Lockers should be located in the vicinity of the fabric section. Small items, such as measuring instruments and cutting, stapling, and setting tools, should be safely stowed in lockers. Needles and spare sewing machine parts should be stowed in a manner to keep dust from them. The number and location of lockers required to satisfactorily stow all necessary items can be determined by the available space in the parachute loft.

PARACHUTE INSPECTION

Parachutes are designed to provide an avenue of escape for pilots and aircrewmen from disabled aircraft. The nature of this lifesaving item leaves no margin for error in the work of the PR. The parachute must be ready to render prompt, efficient, and reliable service at all times.

Parachute inspections must be carefully conducted, insuring comfort, security, rapid

10967

Figure 4-1. —Floor plan for a parachute loft ashore.

10968

positive functioning, and airworthiness of the entire assembly.

FACTORS AFFECTING MALFUNCTIONS

Before inspecting a parachute, the PR must know what to look for. Some of the factors which may cause a malfunction are discussed in the following paragraphs.

Wear

Wear in a parachute is not difficult to detect. It is indicated by chafing at corners or on the outside surfaces where the most frequent contact with moving objects is encountered.

Parts of parachutes and related equipment showing excessive wear should be replaced or repaired, the work to be accomplished at the lowest maintenance level capable of performing the task.

Stains

Stains appear as a discoloration or blemish in the material. Although not all stains are harmful to nylon, they should be considered as harmful agents until identified and proven harmless.

Those stains caused by contact with acid, oil, and salt water are the most harmful to nylon and should be removed as quickly as possible to prevent further deterioration of the material.

PR's must learn to recognize these stains quickly and know the best method of remedying each.

Suspension Lines Out of Position

Be sure that each of the suspension lines is in proper rotation at the connector links and through the canopy. Insure that each unit of the assembly is in its correct position.

Compliance With Current Directives

On parachute repack cycles or when otherwise directed, inspect the parachute assembly and components, for updating and compliance with the latest modifications. For each type of parachute, refer to the Aviation-Crew Systems Personnel Parachute Manual, NavAir 13-1-6.2, and recent Aircrew System Bulletins and changes for all current parachute configurations. Do not permit any local modifications without prior approval of proper authority.

Manufacturer's Errors

When inspecting a new parachute, be especially watchful for errors in the material and workmanship. It is very easy for a mistake to get by in a large plant where many persons are involved in completing a single product. Newness is not necessarily an indication that an object is perfect or even in good condition. Always make a thorough inspection of every part of a new parachute before it is packed for service use.

INSPECTION INTERVALS

All parachutes are subjected to periodic inspections. Inspections must be thorough at all times; no instance of careless treatment or willful neglect of parachute equipment may be allowed to pass unnoticed. The vital function of this equipment must be uppermost in the minds of all personnel concerned. The periodic inspection cycles must coincide with the applicable aircraft inspection cycles specified in the Naval Aircraft Maintenance Program, NavAir Inst. 4700.2 (Series). In no case may the interval between inspections exceed 182 days for the NB-11, 147 days for the LW-3B, and 126 days for all other assemblies.

The different types of periodic inspections are as follows: daily, 7/14 day, original issue/calendar/special, postcombat, and aircraft accident inspections.

Any parachute assembly which requires repacking, maintenance, modification, or repair must be handled at the lowest level of maintenance equipped to satisfactorily perform the work. Mission, time, equipment, trained personnel, and operational needs are the basic considerations involved in determining which level is to be used.

Daily Inspections

The daily inspection must be performed on all in-service parachute assemblies. This inspection must be performed in accordance with local maintenance requirements cards by a representative of the organizational maintenance

10969 10968

activity, the plane captain, or a designated aircrewman. It must be performed daily and following ground transportation of an assembly. This inspection is not detailed, involving only in-place checks for external damage and security of tackings or broken strands in tackings.

Seven/Fourteen Day Inspection

The 7/14 day inspection must be performed on all in-service parachute assemblies by organizational level maintenance activities or an authorized aircrewman.

Parachute assemblies assigned to OV, VA, VF, and VT type aircraft must be inspected every 7 days.

Parachute assemblies assigned to VP, VR, VS, VH, and VW type aircraft must be inspected every 14 days. Assemblies used for training, para-rescue, pathfinding, and reconnaissance teams, and those parachute assemblies not assigned to a specific type of aircraft, must be inspected every 14 days. These inspections include, but are not limited to, emergency aircraft escape assemblies and/or systems, as well as assemblies used for premeditated free-fall or static line parachute descents.

The reserve (emergency) parachute which may form a part of a training type, troop type, or a test assembly must also be included in the inspections. If any damage or contamination is found or suspected, notify maintenance control. Record the completion of inspections on the Parachute Record Card.

Do not open the parachute assembly or damage ripcord safety-ties while performing the 7/14 day inspections.

On all parachute assemblies that employ a metal ripcord handle clip, the ease of removal of the ripcord handle from the metal clip must be checked on each 7/14 day inspection. To perform this examination, carefully remove the ripcord handle from the clip. The ripcord handle should be retained by the clip but removed easily when pulled.

ORIGINAL ISSUE INSPECTION

The original issue inspection is performed at the time a parachute is placed into service. When a parachute assembly is an aircraft inventory item, the acceptance inventory inspection and packing may serve as the original issue inspection. In this case, the records concerning the parachute must be examined. If any discrepancy is found, a special inspection, as discussed later in this chapter, must be performed.

Special Inspection

When a parachute assembly must be inspected at a time other than the aircraft calendar interval, a special inspection must be performed.

Postcombat Inspection

Organizational level maintenance must inspect parachute assemblies for external damage or abnormal condition after each combat mission. When an aircraft has been subjected to gunfire, all parachutes must be examined for damage prior to the next flight. If it is found that bullets or fragments have entered the parachute assembly, remove it from service and perform a special inspection.

Aircraft Accident Report Inspection

Parachutes and related equipment which have been recovered following emergency bailout or ejection must be removed from service and turned in to the nearest supply activity on an exchange basis.

The turned-in parachute must be shipped to the Commanding Officer, Naval Aerospace Recovery Facility, El Centro, California 92243, marked "For Naval Aerospace Recovery Facility Evaluation and Testing."

In accordance with NavAir Inst. 13480.1B, and to provide the Naval Aerospace Recovery Facility with sufficient information to properly evaluate and improve these parachutes for service use, a brief summary of the ejection or bailout must be enclosed with each parachute turned in after emergency use. This summary must contain the following information:

1. Name of activity.
2. Date, time, and place of emergency escape.
3. Serial number and date of manufacture of the parachute assembly.
4. Serial number of the automatic actuator.
5. The name, rank, or rate of personnel involved.
6. Type of aircraft, altitude, and airspeed, if known.
7. Was emergency exit successful in all respects. If not, list difficulties encountered.

TEOU0970

8. Did parachute and actuator function properly?

9. Include remarks or additional information.

Calendar Inspection

The calendar inspection of parachute assemblies is scheduled to correspond with the aircraft calendar inspection. On the calendar inspection all personnel parachutes in service use are opened, and each component part given a complete and thorough inspection. The parachute is then hung in a suitable drying locker to air and dry for a period of 24 hours and repacked for service use. This period may be reduced in the interest of operational effectiveness with the approval of the commanding officer.

When performing the calendar inspection, the following procedure should be followed. If doubt exists as to the serviceability of a parachute assembly, it should be forwarded to the next higher level of maintenance.

PREPARATION.—Open the parachute by pulling the ripcord handle with a suitable scale attached. The maximum pull force is 27 pounds (60 pounds for LW-3B). If the maximum pull force is exceeded, the ripcord pins, cones, and grommets must be inspected for bends, dents, and roughness. Insure that the ripcord cable moves freely in its housing. Inspect the housing for sharp bends or dents, and replace damaged parts as necessary. Silicone spray may be sparingly applied to ripcord parts. On all assemblies with metal ripcord handle clip, reinsert the handle into the clip and seat the handle fully. Reset the scale to read 0. Using a straight, steady pull, remove the handle from the clip. The force required to remove the handle from the clip must be 10 to 20 pounds. If not within limits, examine the clip for corrosion, sharp edges, bends, twists, and dents. The clip may be adjusted by using pliers, taking care not to mar the clip. If any maintenance was performed on the clip, repeat the test.

Examine the webbing for contamination, fraying, loose or broken stitches, cuts, and burns. Replace any damaged stitching; if other damage exists, replace webbing and/or clip.

CAUTION: Before performing the ripcord pull test, insure safety pins are installed on parachute assemblies that employ automatic actuators, ballistic spreading guns, and static line cutters.

The parachute is now ready to be laid out full length on the packing table and the connector links fastened to the tensioning hooks. Engage the hook at the opposite end of the table into the loop of the pilot chute connector.

CANOPY.—Starting at the gore with the nameplate, the two suspension lines attached to the gore are taken, one in either hand, and flicked up and down together so as to trap air beneath the gore. This will reveal any holes or tears in the fabric and straighten out any creases. A careful examination of every part of the gore proceeds systematically up the gore from the skirt. As each section seam is reached, it is thoroughly inspected to detect any signs of broken stitches. The attachment of the suspension lines to the skirt hem of each gore must be carefully examined to determine that the zigzag stitching reinforcement is intact and that the hem is undamaged. The canopy must be examined for stains of all sorts that may lead to deterioration of the fabric. Every effort must be made to keep the canopy clean. Continue this method of inspection until each gore has been completely checked for every possible damage which might endanger the life of a prospective user. Check the peak for attachment of the vent collar and test the vent ring for strength and elasticity by stretching it to its fullest extent.

SUSPENSION LINES.—Examine the connector link for cracks, rust, or corrosion. Check the continuity of the suspension lines and attachment at the links. Check zigzag stitching for defects both in the attachment at the links and at the skirt hem. Carefully examine each suspension line for fraying, projecting loops of thread, friction burns, and stains. This examination may be made by grasping one group of lines and placing them side by side in the hand. Slide the hand underneath the group and inspect about 2 feet, then turn the group over and check the reverse side. Continue this method of inspecting 2 feet at a time until the entire length of both groups have been carefully inspected.

If uneven lengths are found during the inspection of the suspension lines, the parachute must be sent to a depot level maintenance station for correction. Never attempt to shorten or lengthen a suspension line.

PARACHUTE CONTAINER.—Inspect the parachute container for rips, tears, stains, and proper attachment of flaps and hesitator loops. Watch for a bent or broken pack frame, and look at the pack stiffeners for evidence of chafing of

0V60 10971

the fabric enclosures and damage to the stiffeners.

Look closely at the attachment of the harness to the container. Be sure that all stitches are intact and made in accordance with latest directives. See that the end tabs are not damaged and are secured properly to the end flaps. The metal end tab must be positioned with the concave side toward the container when in position over the cone. If a cone is rough or badly damaged it must be replaced. Watch for damaged or unserviceable grommets and ripcord protector flap fasteners, and check pack opening bands for security of attachment of the eyes and general condition.

HARNESS.—When checking the harness and flit web assemblies, examine the hardware for corrosion, rust, cracks, breaks, bends, or other damage, and ease of operation. Check the webbing for fraying, wear, abrasion, stains, defective stitching, and twists. Check the harness, insuring that the webbing straps of the assembly follow the proper sequence.

PILOT CHUTE.—Examine the pilot chute for stains, broken or loosened stitching in the seams, and holes or tears in the canopy. Check closely the coiled spring for breaks, bends, and proper spring tension. Check the connector cord for length of cord and loops and for damage and security of the connecting knots.

RIPCORDS AND HOUSINGS.—The ripcord housing should be checked for security of the end ferrules to the coil housing, for breaks, crushing, or other deformation of the housing. Check the proper location and security of attachment.

The ripcord is checked for proper length, bent, broken, or rough locking pins, the swaged joints for attachment, and the cable for frayed strands and rust or corrosion.

SEAT CUSHIONS/PADS.—Look closely at the cushions and back pads for overall condition. See that all keepers are secure and that all snaps are in good working order and fastened properly. A defective or missing snap fastener should be repaired or replaced, and damage to the cover or weakened stitching should be repaired.

CONTAMINATION INSPECTION.—All parachute assemblies must be carefully inspected for evidence of contamination. When a discoloration appears on the parachute container, canopy, or related equipment, the stain should be identified and remedied as soon as possible. The identification of these discolorations or stains may be accomplished by several methods, the best of which is to identify by sight the more common stains as follows:

1. Acid stains appear as a gray putty-colored stain or a powdery ash, depending upon the strength of the acid solution which made the stain.

2. Salt water stains are generally characterized by the appearance of a white crystalline substance on the surface of the material with a slight discoloration in the area.

3. Oil and grease stains have a greenish color and produce an oily or greasy feeling when touched or rubbed between the fingers.

Parachutes and components stained by any of these or other injurious substances must be cleaned as described in chapter 11 of this manual. If the contamination cannot be removed, the parachute assembly must be forwarded to a depot level maintenance for additional cleaning. Attach a report of the nature and location of all stains.

SERVICE LIFE CHECK.—The service life of a parachute assembly or subassembly is 7 years from the date it was placed in service (opening manufacture's package), or 8 1/2 years from the date of manufacture, whichever occurs first. When an assembly or subassembly reaches the service life limit, it must be removed from service and forwarded to supply for disposition.

NOTE: The service life of troop, training, and NB-5 assemblies is 10 years from the date of manufacture.

When a parachute is placed in service from stores, the month/year of opening the manufacturer's individual shipping container must be stenciled on the parachute's nameplate gore. Letters must be 1/2 inch high and made with blue parachute marking fluid (MIL-I-6903). The term "date placed in service" followed by month/year notation must be placed directly below the nameplate.

When an in-service parachute lacks a start of service date, the service life will expire 7 years from the date of manufacture.

NOTE: On MBEU assemblies if determination of age of a canopy is unclear, as reasonable an estimate as possible must be made from information on the Parachute History Card and other available parachute records. All MBEU canopies manufactured after June 1967 have a date of manufacture located on gore number 1 near the skirt hem.

If no date of manufacture is available on a subassembly, the date marked on the parachute canopy will apply to the subassembly.

10972

PARACHUTE MAINTENANCE RECORDS AND FORMS

The records and forms used by the Aircrew Survival Equipmentman to provide a systematic means of control will be discussed in this section.

Parachute Record Card

The Parachute Record Card, NavAir 13480/1, is used to record the 7/14 day inspection and the normal inspection and repacking data including the automatic actuator cartridge expiration date and load lot number. Since the repack cycle differs for each type of parachute assembly, depending on which type aircraft the assembly is in, this information must be recorded on the upper right-hand corner of the card front. When the Parachute Record Card is completely filled, it must be replaced by a new card. Review the card and compare it to the Parachute History Card to verify that all entries have been recorded. The Parachute Record Card is shown in figure 4-2.

Parachute History Card

The Parachute History card, NavAir 13480/2, contains all information found on the Parachute Record Card, including the repack cycle information in the upper right-hand corner of the card front. The Parachute History Card is shown in figure 4-3.

In cases where the aircraft inspection cycle is changed, a notation must be added to the card referencing the specific entry in the Aircraft Log Book authorizing the change. In addition, all modifications performed on a parachute assembly must be recorded on the Parachute History Card. When the card is completed, it is stapled to the back of the new card. The Parachute History Card is maintained at the organizational level.

Information concerning repacking, modifications, and repairs must be extracted from the Work Request, NavAir 4710/7, after work at a higher level is performed and entered on the card. Whenever a parachute assembly is transferred from one unit to another, an updated parachute History Card must be forwarded to the receiving unit, attached to the parachute assembly. If the parachute is an aircraft inventory item, the Parachute History Card is inserted into the Inventory Log book and forwarded.

Canopy Damage Charts

Whenever a canopy is inspected and found to need repairs, the appropriate Canopy Damage Chart must be filled out. A Canopy Damage Chart for 24- and 28-foot canopies is shown in figure 4-4.

If repairs cannot be accomplished locally, the chart must accompany the canopy to the next higher level of maintenance. This form must not be discarded. Upon completion of the repairs, the Canopy Damage Chart must be affixed to the Parachute History Card.

NOTE: DO NOT MAKE ANY MARKS ON THE CANOPY.

Until Canopy Damage Charts are published as NavAir Forms, the examples contained in the Aviation-Crew Systems Personnel Parachute Manual may be locally reproduced.

Shop Process Cards

Shop Process Cards will be made available in the near future. These cards will contain minimal shop procedures. Clearances, tolerances, diagrams, and equipment required will be included. The Shop Process Cards will be arranged in a logical sequence to aid the Aircrew Survival Equipmentman.

SURVEY

To survey is to examine, inspect, or consider carefully. Therefore, survey boards are composed of an officer (or officers) appointed by the commanding officer to examine, inspect, or consider carefully the facts surrounding an accountable item which, for reasons of loss, damage, deterioration, or normal wear, must be expended from the records.

There are two types of surveys—formal and informal. The choice of survey to be used is designated by the systems command concerned with the item to be surveyed, or by the commanding officer. The formal survey is made by a commissioned officer appointed by the commanding officer, or by a survey board appointed by the commanding officer and consisting of three officers, one of whom must be a commissioned officer.

The custodian of an item to be surveyed prepares a written statement of the circumstances

10973

10973

Figure 16-8.—Sweep clamp, shutoff, charging clamp, and bootstrap amplifier.

a time base for the measurement of range. However, this sawtooth must be amplified before it is applied to the deflection system of the indicator. The sweep amplifier circuits also provide a means of feedback to improve the linearity of the sweep voltage. The feedback voltage is taken from the sweep driver stage and fed to the bootstrap amplifier V11.

The basic circuits utilized in the sweep amplifier circuits are discussed in detail in Basic Electronics. Therefore, only the operation of the sweep amplifier and its waveforms are discussed. Figure 16-10 is an illustration of the waveforms throughout the sweep amplifying chain. Reference to waveforms illustrated are by number as shown. Figure 16-11 is the schematic of the sweep amplifying circuits and should be referred to for the following analysis.

As stated previously, the positive sawtooth on a pedestal is coupled directly from the plate of the sweep clamper V10A to the grid of the first sweep amplifier V12 (waveform (1), fig. 16-10). Note that the cathode of V12 is returned to ground through the sweep driver's cathode resistor. This provides degenerative feedback which improves the linearity of the amplifying circuits. This should not be confused with the feedback loop through the bootstrap amplifier to the sweep generator. Feedback within the sweep amplifiers aids in eliminating distortion that may be generated within the sweep amplifier circuits. The feedback voltage is illustrated by waveform (3). The relative amplitudes of the two signals applied to V12 should be noted. Thus, the output of V12, because of the feedback voltage, has been greatly reduced.

A linear negative sawtooth on a pedestal is coupled to the grid of the second sweep amplifier V13. The oscillation suppression circuit, consisting of C25 and R48 in the grid circuit of V13, acts as a low impedance path for high frequency oscillations. (NOTE: A sudden change in input voltage such as the trailing edge

CHAPTER 5

PARACHUTE PACKING AND RIGGING

Packing is more than a matter of inserting a canopy into its pack. It is a combination of rigging, inspecting, and packing. However, most of the inspection phases of the operation can be carried out independently. Thus, inspection was treated separately in the previous chapter. The perfect working of the parachute depends on the methods used in the rigging and packing processes, proper inspection, and configurations. If a thorough and reliable packing procedure is understood, the PR should be able to apply that knowledge to any type of parachute.

The beginner may take as long as 45 minutes to pack a parachute. A large part of that time will be spent on the stowage of suspension lines. After a few weeks practice, this time will shorten to an average of 20 minutes or less until peak performance is reached. Due to the uniform system taught to the Navy Aircrew Survival Equipmentman, any two men can soon work in harmony and form a good packing team. It should be kept in mind that speed is secondary to accuracy. A good Aircrew Survival Equipmentman will recognize his best packing speed consistent with quality and settle down to a good reliable pace that guarantees perfection. As each phase of the packing and rigging is completed, a collateral duty inspector must examine the finished work and verify correctness of the work.

RIGGING TOOLS

As a general rule, rigging a parachute in preparation for packing involves tacking various appendages and assemblies to the parachute. Making these tackings necessitates the use of several special type handtools common only to hand sewing.

The most useful of these—the sail needle—is used in passing the thread or cord through the materials being tacked. The difficulty encountered in passing the needle through the various weights and thicknesses of webbing, fabric, and/or canvas makes the use of other tools such as the awl, the sewing palm, and smooth-jawed pliers necessary in rigging a parachute for packing.

SAIL NEEDLES

The most distinctive feature of the sail needle is its broad, three-edged shape in relation to its size. Although the shape of the sail needle sometimes prevents its use in hard, closely woven fabrics, it is still the most useful hand sewing needle for parachute maintenance. It is the toughest needle available and will take a lot of rough use without breaking at the eye, as do many of the round needles.

Sail needles are issued in various numbered sizes. The larger the number, the finer the needle. The most popular sizes are the 14 and 16, shown in figure 5-1 along with the No. 10 size.

When selecting a needle for use, remember that the eye is intended to offer just enough resistance to the thread or cord to keep the needle in place and prevent it from sliding out of position. The cord or thread should pass freely through the eye of the needle. Difficulty is encountered in passing a needle through a piece of cloth when the needle is threaded with a cord too heavy for the eye. The choice of size therefore depends on the size of thread or cord to be used in sewing. An improper selection will interfere with speed and efficiency and increase the possibility of damaging the material.

SEWING PALM

The sewing palm is a small metal disk insert, stitched in a leather glove type device. It is designed to be worn in the palm of the hand

10978

PR.145

Figure 5-1.—Sail needles.

and is used to aid in pushing a sail needle through the material being sewn or tacked. (See fig. 5-2 (K).)

AWL

The awl (I) is another instrument used as an aid in sewing heavy material where pushing the sail or hand sewing needle becomes difficult. It is a sharp pointed instrument, with a handle attached, used for punching holes in a fabric or material prior to inserting the needle.

PLIERS

Other tools which aid in hand sewing are pliers (H), either the needle-nosed or the combination slip-joint type. In either case they must by smooth jawed to prevent damage to the needle.

Among miscellaneous rigging tools needed in the parachute loft are a sharpening stone, for keeping needles, awls, and knives in tip-top condition; a knife for miscellaneous cutting jobs; and a soldering iron or other suitable instrument for searing nylon.

SPRING SCALE

The spring scale is an instrument used in the ripcord pull test. It measures and records the amount of force required to remove the ripcord pins from the locking cones. (See fig. 5-2 (N).)

All parachute assemblies are subjected to a ripcord pull test prior to being unpacked for inspection. The maximum pull force allowable is 27 pounds (60 pounds for the LW-3B assembly).

NOTE: Due to the employment of pyrotechnic devices on various assemblies, the following precautions are cited to insure safety of personnel performing inspection and maintenance operations:

1. NB-11 assembly: Carefully raise the folded canopy at the top end of the container, exposing the fail-safe ballistic spreading gun. Open the fasteners on the extractor sleeve and insert the safety pin in the gun.

2. NB-7E and LW-3B assemblies: Carefully remove the tacking from the static line cutter cover and slide back the cover. Insert the safety pin in the static line cutter.

3. NB-5, NB-6, NB-7, NB-7D, NB-7E, NB-8, NB-9, NB-10, NB-11, and NS-3 assemblies: These assemblies may employ cartridge operated actuators. Insure that the automatic actuator arming cable is not pulled while the actuator is armed. To dearm, open the actuator pocket slide fastener and base plate protector flap. Remove the actuator from the pocket. Remove the locking screw and slide the barrel, piston, and the receiver from the cover assembly. Hold the arming pin in position until the barrel and piston have been removed from the receiver. Remove the cartridge from the barrel immediately after the barrel and piston assembly are removed.

PACKING TOOLS

The packing tool kit (fig. 5-2) reveals a simple array of tools. The individual tools, while unimpressive in appearance, are quite specialized in application. These tools cannot be drawn from stock individually, but may be drawn through supply as a kit. Some of these tools may be made locally.

The long bar (A) is a bar of aluminum approximately 1 5/8 inches wide, 18 inches long, and one-fourth inch thick. The edge must be rounded and the entire surface smoothed and polished to prevent damage to the fabric of the canopy. It is used to make the folds in the canopy and to aid in smoothing out the pack.

The fid (B) can be made of aluminum or of wood. It is about 8 inches long and the same

10979

Figure 5-2.—Packing and service tools. (A) Long bar; (B) fid; (C) suspension line hook; (D) temporary locking pins; (E) suspension line holder; (F) shot bag; (G) shears; (H) pliers; (I) awl; (J) tension hooks; (K) sewing palm and needle; (L) pilot chute guide tube; (M) pilot chute locking pin plate; (N) spring scale; (O) parachute packing board.

10980

approximate width and thickness as the long bar. It is used in smoothing out the pack and tucking in the flaps.

The suspension line hook (C) is made of a suitable metal to give it the strength and durability needed to pull the suspension lines through the hesitator loops when stowing the lines in the pack. It must be free from all burrs and rough edges.

Temporary locking pins (D) are made of 0.080 stainless steel wire in the general configuration shown in figure 5-2. They are used to secure the pack in the temporarily closed position, after it has been placed in the container and before the ripcord has been inserted in the locking cones.

The suspension line holder (E) is made of aluminum and is designed in the general shape of three fingers. This design affords two slots between the "fingers" into which the suspension lines can be temporarily placed after the continuity has been checked. When placed in these slots and held in place by shot bags, they will remain straight until ready to be stowed in the hesitator loops.

Shot bags (F) are canvas bags approximately 1 inch in diameter and 16 to 18 inches long. They are filled with lead shot and provide weight to hold the canopy and suspension lines in position during the packing process.

The parachute packing board (O), shown in figure 5-2, is a tool used to tension the suspension lines with the antisquid lines attached to the connector links. Basically it consists of a board and two large spools. The packing board is used when packing the NES-8 and MBEU type parachutes.

Due to the light weight of nylon and its susceptibility to damage, special treatment must be given to preclude any action which might be injurious to the material of the parachute assembly. Particular attention should be given to any tool which might come in contact with the canopy or suspension lines. Burrs and rough areas on any of the metal parts must be polished down, using 0 grit emery cloth.

REMOVING SUSPENSION LINE ENTANGLEMENTS

Suspension line entanglements (dips and twists) are caused by the canopy or harness passing in between the suspension lines. In chapter 3 we studied the method of attaching the suspension lines to the links and in turn how the links are attached to the lift webs of the harness.

In separating the lines to check for dips and twists, first find the gore bearing the nameplate and place it uppermost in the center of the table. Separate the suspension lines into two equal groups, left and right, by counting 14 lines on each side of the nameplate gore of a 28-foot diameter canopy. If any lines are tangled, the lines will not run clear from connector link to canopy skirt, and the dip or twist must be removed.

A DIP is a line or group of lines passing THROUGH another group of lines. A TWIST is a line or group of lines passing AROUND another group of lines. Do not pack a parachute with a dip or twist in the suspension lines. This would prevent proper opening of the parachute and might very well result in the death of a pilot or crewman.

Most twists may be removed by simply unwinding the lines in the opposite direction of the twist, but dips present a much more difficult problem. There are two commonly used methods by which dips may be removed—the two-group method and one-line method.

The two-group method is satisfactory when there are only a few dips in the suspension lines. With the parachute hooked up loosely, separate the suspension lines at the skirt into two groups. Hold one group in each hand and work toward the harness, separating the two groups as you go. This forces the dips down to the link end of the suspension lines and makes it possible to see them clearly. Still holding the suspension lines, have the helper take the suspension line connector links off of the spreader bar and pass the harness and container through the suspension lines wherever one line passes through the rest. Care must be used not to tangle the harness while passing it through the lines.

The one-line method of removing dips is usually used if there are a large number of dips and twists in the lines. However, either method may be used according to your own personal preference.

Lay out the parachute as for the two-group method. Pick up either line No. 1 or line No. 28 and, while holding it loosely in one hand, walk toward the harness. With the other hand, form a loop of all the lines around the hand. Hold the single line and place all the lines that go over this over the arm and those that pass under the

line, under the arm. Pass the container and harness through the loop thus formed.

The last step in removing dips and twists from the suspension lines by either method is to check the lines for continuity. This is the only positive method of determining if the job has been properly done. To check the lines for continuity have the helper stand at the skirt hem and, starting with suspension line No. 1, lift the lines away from the group one at a time while checking the same line at the connector link to make sure that each line is in sequence.

CHAINING SUSPENSION LINES

Suspension lines are chained by tying a series of hitches to form a chain. Grasp the lines at a point near the skirt hem and make an overhand knot. Reach through the loop of this knot and grasp the lines again and pull them through the loop. This makes the first hitch. Tighten the loop of the first hitch and repeat the process of reaching through the loop of each successive hitch and pulling through another loop until the entire length of the suspension lines is chained. Pull all of the chained lines through the loop of the last hitch to complete the chain (See fig. 5-3.)

PR.147

Figure 5-3.—Steps in chaining suspension lines.

KNOTS USED IN PARACHUTE MAINTENANCE

In addition to the overhand knot used in chaining the suspension lines, PR's should learn to tie the half-hitch (a variation of the overhand knot). The half-hitch is used to make the ripcord safety tie and also used with the clove-hitch in securing the suspension lines to the connector links. Other knots which PR's need to know are the square knot, bowline knot, fisherman's knot, surgeon's knot, and lark's head knot.

The square knot may be used in most cases in which a knot is required and a particular knot is not specified. The bowline knot is used to secure the pilot chute connector cord to the apex of the parachute. The lark's head knot is used to attach the pilot chute connector cords on the MBEU assemblies. The fisherman's knot and the surgeon's knot are used in tying off various tackings on parachute harness and containers where a knot that will not slip is needed. (See fig. 5-4.)

HANDLING PACKED PARACHUTES

The most effective way to explain the subject of handling packed parachutes is to list a series of general rules in the form of DO's and DON'Ts.

1. Do not pick up a parachute by its lift webs or ripcord handgrip. Lift web tackings break relatively easy and when they do, the suspension lines are almost certain to become disarranged. Carrying or attempting to carry a parachute by its ripcord grip will always result in a premature opening.
2. Do not place a parachute near any source of heat. Heat will cause brittleness in nylon fabric.
3. Do not place a parachute in or near any source of dirt, grease, or oil. Stains can be extremely harmful to fabrics when they contain strong acids or alkalies.

10982

.8001

PR.148

Figure 5-4.—Knots and hitches used in parachute maintenance.

10983

Figure 16-9. —Waveforms of the sweep generating circuits.

of waveform (1) may shock-excite an amplifier into oscillating.) The second sweep amplifier also amplifies and inverts the signal as shown by waveform (4). Its output, a positive sawtooth on a pedestal, is fed to the grid of the cathode follower V15.

The cathode follower is used to match the high impedance output of the second sweep amplifier to the low input impedance of the sweep driver. In static condition, V15 is biased negative by the voltage divider network in its grid circuit. However, with the plate of V15 connected to a positive 150 volts and its cathode connected through R53 to a negative 300 volts, it will conduct and bias V16 at approximately minus 40 volts. The diode V14A is used as a clamper to return the grid to its static potential following each sawtooth input.

The sweep driver receives the positive trapezoidal voltage (sawtooth on a pedestal) from the sweep cathode follower. As the slope of the waveform is reduced (longer ranges), the pedestal amplitude is also reduced.

The output transformer T2 is the plate load for the sweep driver. As shown in waveform (6), a linear positive sawtooth of current appears in its primary with each input. It is combined with a signal from the compensating gate driver which is discussed later in this chapter. Resistors R61 and R62 are in parallel with the primary of T2 and are used to dampen oscillations of the transformer. Degenerative feedback resulting from the unbypassed cathode resistor R56 also aids in reducing oscillations as well as providing a source of signal which is fed back to earlier stages. A sweep reference level signal is also fed from this point to the sweep compensating gate circuit.

Bootstrap Amplifier

Now that the basic operation of the sweep circuits has been discussed, the action of the bootstrap amplifier will be explained. For the following discussion refer to figure 16-8.

The input to the bootstrap amplifier (applied to the cathode) is a linear positive sawtooth voltage from the cathode of the sweep driver. The amplitude of the input signal is proportional to the output current of the sweep driver. The

1096

4. Do not drop a parachute. Dropping a parachute can bend or break the metal components and perhaps cause failure of the entire assembly.

5. Do not leave a parachute where it is likely to get wet.

6. Do not leave a parachute where heavy objects can be dropped or placed on it. Permitting a parachute to be carried in a cargo net along with squadron cruise boxes or similar gear displays poor handling techniques.

7. Use the chafing bag to cover the parachute when it is expected to be kept out of service for a considerable amount of time.

8 Use utmost caution when handling parachutes with installed cartridge activated devices.

9. Be prepared to give brief lectures instructing personnel on how to handle parachutes.

Figures 5-5 through 5-8 illustrate the best methods of carrying packed parachutes when rigged with and without the pararaft kit.

CHAFING BAGS

The parachute chafing bag, closed with two long slide fasteners, provides ample stowage portection for the parachute in a packed or unpacked condition. The slide fasteners, when opened, offer a large cavity capable of receiving most parachutes. The basic rules for stowing a parachute in the chafing bag are:

1. Chain the suspension lines.
2. Place the harness in the bag first.
3. Let the pack act as the separator between the canopy and hardware.
4. Accordion pleat the canopy into the bag.
5. When appropriate, and for very short periods in transit, compress the pilot chute into the bag, using the side as a backstop for the top of the pilot chute. Otherwise, disengage the pilot chute and stow separately.
6. Be careful when closing the bag and do not catch the canopy fabric in the slide fasteners.
7. Do not stow the bag directly on the floor.
8. Make certain that the bag is properly stenciled or tagged for identification purposes.

SHIPPING CANS

Parachutes are shipped from the manufacturer in sealed cans and may remain in the shipping can as long as they are not bent,

PR.149

Figure 5-5.—Method of carrying the chest type parachute with or without the pararaft kit.

PR.150

PR.152

Figure 5-8.—Method of carrying the back type parachute when rigged with the pararaft kit.

crushed, or ruptured. Once the can is opened and the plastic liner is broken, the parachute should be placed in service, or placed in a chafing bag for stowage.

SAFETY PRECAUTIONS

Extra care must be given to the handling of packed parachutes, especially on the flight line. Instruction of squadron personnel in proper handling techniques is the responsibility of the PR.

Extra instruction should be directed to plane captains since they are required to handle parachutes frequently. The following are some of the precautions which should be observed by all personnel handling parachutes:

Parachutes should not be hauled around on dirty bomb trucks, trailers, and the like.

Parachutes should not be placed on the wing or tail surfaces of aircraft. They should be placed immediately in the seat or other storage space in the aircraft. Parachutes must never be placed in a wet seat.

Seat type parachutes should be carried over the shoulder, with the hand through the grip, locking it in its pocket as shown in figure 5-6.

CHAPTER 6

PACKING AND RIGGING THE CHEST TYPE PARACHUTE

The NC-3 personnel parachute assembly is a chest type parachute used primarily in transport and patrol type aircraft. The advantage of the NC-3 in these types of aircraft is mobility, as aircrewmen ordinarily wear only the harness during flight. With the quick-fit harness, aircrewmen can be ready for bailout in a matter of seconds.

The NC-3 parachute assembly includes a 28-foot diameter, flat, circular, nylon canopy with 28 gores. The canopy is packed in a container assembly secured to the aircrewman's chest by means of a harness assembly.

Two different configurations of the NC-3 parachute are in service. These configurations are (1) the basic NC-3 assembly; and (2) the NC-3 assembly with the standard soft pack attached.

The standard soft pack is one of several types of packaged LR-1 life rafts.

RIGGING THE BASIC NC-3 ASSEMBLY

At the time of issue, the NC-3 parachute assembly must be rigged as described in the following paragraphs. Subsequent rigging of the NC-3 assembly must be accomplished in the same sequence, omitting the nonrequired steps. It is not always necessary to break and remake the tackings that go together in the rigging of certain appendages.

INITIAL PREPARATION

Lay out on the packing table all required packing tools, inspect the packing tools for serviceability, and count and record the number of packing tools to be used.

Lay out the parachute canopy full length on a clean packing table. Position the canopy gore containing the nameplate uppermost in the center of the packing table. Separate the suspension lines into two groups, counting 14 lines on each side of the nameplate gore. If necessary, attach the pilot parachute to the canopy peak using 1,000 pound tubular nylon, 1/2 inch width. Measure and cut the pilot parachute connector cord to a starting length of 42 1/2 to 43 1/2 inches; the tied off, finished length must be 21 to 22 inches.

Arrange the two groups of 14 suspension lines on each side of the nameplate gore in accordance with figure 6-1 as viewed from the connector links. The numbers in figure 6-1 illustrate the location and orientation of the suspension lines when attached to the skirt hem and the connector links.

Place the connector link holding suspension lines 1 through 7 on top of the connector link holding the suspension lines 8 through 14. Place the connector link holding the suspension lines 22 through 28 on top of the connector link holding the suspension lines 15 through 21. Connect these two groups of connector links to their respective tension hooks on the packing table.

NOTE: The knurled portions of the connector link yoke and plate assemblies must face up and the screwheads must face outboard.

ATTACHMENT OF BACK CUSHION TO THE HARNESS ASSEMBLY

Lay out the harness assembly on the packing table, oriented in such a way that the wearer would be facing down on the packing table with his head towards the canopy, and position the back cushion underneath with the keepers released. Secure the diagonal backstraps under the upper corner keepers and the horizontal backstrap under the two bottom center keepers.

SUSPENSION LINE CONTINUITY CHECK

Attach a tension strap at the canopy vent lines and tighten. When viewed from the riser

10987

PR.153

Figure 6-1.—Arrangement of the suspension lines on the connector links and the canopy skirt hem.

end of the packing table, the suspension lines must be arranged on the skirt hem and the connector links as shown in figure 6-1. The suspension lines must run free from the skirt hem to the connector links without dips or twists.

The packer must start with suspension line number 1 on the left side of the nameplate gore and work through line 14. The helper must be positioned at the connector links to check continuity of the suspension line selected by the packer. The same procedure is used on the right side of the nameplate gore except that the packer must start with line number 28 and work through line number 15.

ATTACHMENT OF CONNECTOR LINKS TO THE RISER ASSEMBLY

Position the riser assembly at the connector link end of the suspension lines. The spring loaded levers of the quick connector snaps must face up and the corresponding lift webs must be placed on top of each other.

Remove the connector link yoke and plate assemblies. Insert the bottom connector links into the bottom lift web loops and the top connector links into the top lift web loops. Reattach the yoke and plate assemblies and tighten screws to a torque value of 20 to 25 inch pounds.

ATTACHMENT OF THE PARACHUTE CONTAINER TO THE RISER ASSEMBLY

Position the container under the riser assembly, with the inside facing the packing table and the ripcord pin protector flap facing the canopy. The riser assembly cross connector strap must be positioned on top of the container, just inside the container frame, with the spring-loaded levers of the quick-connector snaps turned away from the container.

The NC-3 lift web assembly tacking must be very strongly made to hold the pack securely while the parachute is being worn and at the crucial time of egress from the aircraft. This tacking must be drawn up tightly to prevent slippage during hookup to the harness.

To make the tacking, position the container on the end with the side flap with locking cones on the table and the lift webs inserted through the slots on the upper edge of the container.

With the container and the riser in position, connect the container and riser as shown in figure 6-2.

Tack the quick connector snaps to the container bottom using waxed nylon 6-cord, doubled. Tie a simple overhand knot in the end of the cord to anchor when starting the tracking.

Starting from the inside of the container (1), butterfly tack through the left webs and around the snap slot at one side of the shank (2), around the snap hook (3, 4), through the inside of the container, and around the snap slot at the opposite side of the shank (5, 6). Pull the thread tight and tie off the ends with a surgeon's knot followed by a square knot, ending on the inside of the container.

PACKING THE NC-3

After the parachute has been inspected and all discrepancies corrected as outlined in chapter 4, then aired and dried as described in chapter 5, it is ready to be repacked.

1. Container.
2. Shank.
3 & 4. Snap hooks.
5 & 6. Snap slots.

PR.154

Figure 6-2.—Lift web tacking to the NC-3 parachute container.

The first step is to dust off the packing table. Then, grasp the lift web section and hold it at the packing end of the table while the helper pulls the apex of the canopy toward the opposite end. This will remove the chaining from the suspension lines and stretch the chute to its full extent on the table.

Remove dips and/or twists from suspension lines and lift web assembly. Attach connector links to the tensioning hooks (on the packing end of the table) and engage the hook at the opposite end of the table into the loop of the pilot chute connector cord at the point of encirclement of the suspension lines. (See fig. 6-3.)

Apply only enough tension at the peak to straighten the chute out on the table. The helper should then straighten the vent hem by entwining his fingers through the suspension lines and working them (the lines) back and forth through the loop in the pilot chute connector cord until the vent hem is straight. Manipulating the vent hem in this manner will usually straighten both vent hem and skirt hem.

NOTE: It is very difficult to straighten a vent hem when too much tension has been applied.

Check the information found on the nameplate of the canopy and compare with that found on the Parachute Record Card, NavAir Form 13480/1 and the Parachute History Card, NavAir Form 13480/2.

After the vent hem has been properly straightened, apply more tension at the peak. The exact amount of tension necessary for whipping and folding of the canopy cannot be measured, since the tension varies with the personal wishes of the packer. The chute should be tight enough to draw the suspension lines to the center of the table, but not so tight as to be difficult to hold up to shoulder level while whipping and folding the canopy. (See fig. 6-4.) Both members of the packing team should be able to see the entire gore on the inside when the suspension lines are held at shoulder level. This is an instance in which personal experience is necessary to find the tension which suits you most. Practice packing (especially stowing suspension lines and whipping and folding the canopy) until you develop skill and dexterity of movement.

PR.155

Figure 6-3.—Attaching peak of canopy to tensioning device. Do not attach tensioning hook to the suspension lines. This could cause damage to the lines.

PR.156

Figure 6-4.—NC-3 under tension and ready for whipping and folding.

10989

10988

The next step is to whip and fold the canopy. The packer and helper should work simultaneously from opposite sides of the table at the skirt hem. In beginning the whipping and folding, grasp the two top inboard lines and look back to the links to make sure that the lines are free and clear of entanglements. Raise the lines to a level where the inside of the canopy can be clearly observed to the peak. Visually follow the skirt hem to the next suspension line. Pick up this line and swing it in a wide arc toward the person on the opposite side of the table, bringing it up to shoulder level and holding it in this position. Look down this line on the inside of the canopy to the peak and make sure that no folds from the previous gore have overlapped the suspension line in view. Repeat this process throughout the canopy until each gore is folded in half and each suspension line is held in place in its proper rotation. Fold each gore until all lines have been taken up by the packing team. When these folds have been made, there will be two gores remaining between the two sets of suspension lines which have not been folded. Stretch the two sets of lines to the outermost edges of the packing table, as shown in figure 6-5. Each member of the packing team should grasp all of the folds at their outer edge and grip them firmly. While holding the suspension lines at the edge of the table, move the folds up and down rapidly in a whipping motion. This motion will assure that most of the wrinkles put into the fabric by the folding action are removed.

To make the last two folds, the packer reaches over the suspension lines with his left hand and grasps the center of the top gore, while the helper reaches underneath the lines with his right hand and catches the center of the bottom gore. On a signal, both packer and helper swing their group of suspension lines in an arc toward the center of the table (the packer arcs downward and the helper upward) while at the same time pulling the top and bottom gores to the outer edges of the table. (See fig. 6-6.)

PR.157

Figure 6-5.—Suspension lines stretched to outer edge of table in preparation for whipping the folds.

10991

10990

PR.158

Figure 6-6.—Completing last two folds of canopy.(A) Gores being grasped in the center prior to moving suspension lines to center of table. (B) Lines brought to the center and skirt hem folds brought out in the opposite direction.

10991

The last fold on the helper's side is made on the bottom of the other folds. It therefore requires special attention in straightening all wrinkles from skirt to peak.

Insert the suspension lines in the slots of the suspension line holder and place a shot bag across the lines to hold them in place. The lines may now be released by both packer and helper. Place a shot bag on the folds of the canopy on the packer's side. Whip all of the folds on the helper's side to the packer's side, except the bottom one. The packer should remain at the skirt hem to hold the folds and suspension lines in position while the helper (starting at the skirt hem) pulls the bottom fold out to its proper position throughout the length of the canopy. NOTE: Do not pull or brush too hard on this fold, or the opposite fold may be disturbed. When the helper reaches the peak, the packer then flips all of the folds, positioned above the shot bag, back to their original position on top of the bottom fold on the helper's side of the table. The helper then proceeds to brush out any remaining wrinkles in the folded canopy.

Figure 6-7 illustrates the method of folding the skirt hem back in preparation for straightening, and figure 6-8 shows the method of straightening.

PR.159

Figure 6-7.—Folding the skirt hem in preparation for straightening. Before attempting to straighten the skirt hem, grasp the folds of the skirt at the corners and fold them back out of the way.

Before stowing the suspension lines the canopy must be folded as shown in figure 6-9.

The packer should sign inside Parachute Record Card while the helper releases the tension at the peak very slowly and carefully. A sudden release might disturb the canopy folds. Unhook the hooks, or tensioning device, from the connector links and prepare to stow the suspension lines. Place pilot chute on top of canopy. This prevents it from falling off the table while stowing lines.

The pack should be as level as possible on the table to provide an even working area when packing the chute. It can be leveled by inserting a wooden leveling block or an old foam rubber seat cushion under the pack and tucking the flaps in around it to hold it in place. By having this added elevation, the packing hook is easier to manipulate and the lines are easier to stow in the hesitator loops.

Stowing suspension lines consumes more time than any other step in the packing process, because they must be stowed as straight as possible and absolutely free of twists and entanglements. Stowing them properly requires deft, decisive movements and skill, acquired only by diligent practice. Suspension lines become entangled very easily; therefore, extra caution must be used when stowing to keep them running straight and without tangles between the loops. The shot bags are left on the canopy while stowing the lines. This, coupled with drawing only enough line to form the bight being taken, keeps enough tension on the lines to aid in keeping the lines straight.

Once the hook is engaged in drawing a bight of the lines through a hesitator loop, do not permit the tip to lose contact with the bottom of the pack. This action will prevent "dropping" a line, which could cause a "line-over" during a descent.

The packer stows the lines while the helper holds the pack steady in the center of the table and assists with the stowing by holding the bights of the suspension lines in place as they are stowed. The proper method of stowing suspension lines is illustrated in figures 6-10 and 6-11. When making the first bight, bring the

PR.160

Figure 6-8.—Straightening skirt hem. Aline each fold one upon the other until all are nearly in place. Count the folds while straightening to be sure that an equal number of folds fall on each side of the suspension lines.

lines up to the first hesitator loop. This is the loop nearest the helper's left hand when he is in position for packing. Insert a packing hook through the loop from the outside edge of the pack. Engage the hook in the lines and draw them through the loop. The completed bight should extend about 1 inch beyond the loop.

The second bight is made by inserting the packing hook in the hesitator loop directly opposite the first, then carefully estimating the amount of suspension lines needed to make the bight and grasping the lines at this point. Without twisting the lines, lay them up on the container and engage the hook at the point decided in your estimate of length. Pull this bight through the loop. Repeat this process of inserting the bights of lines alternately from one side to the other until all 16 hesitator loops are filled.

After the last bight has been placed in the hesitator loops, check for twists and dropped lines. Remove all wrinkles from the hesitator loops, using the temporary locking pins as a straightening tool. There should be 15 (±3) inches of line remaining between the skirt hem and the last bight taken. This line permits bringing the skirt up to the far edge of the pack. (See fig. 6-12.)

Proceed with the packing operation as illustrated in figures 6-13 through 6-26.

Caution the helper not to hold down or draw back on the long bar while bringing the skirt up on the pack, but to follow the motion of the lines. Holding down or drawing back will cause the skirt to tuck under and may pull the last bight of suspension lines out of the hesitator loop.

When the helper is certain that the skirt is in position at the edge of the pack and the suspension lines have not been disturbed, he withdraws the long bar and places it on top of the folded canopy in preparation for the next fold. The packer checks the long bar position for alinement. The bar is held to produce a clean fold over the edge of the frame. If the bar is held out too far from

10993

10993

Figure 16-10. —Waveforms of the sweep amplifying chain.

output of the bootstrap amplifier is also a positive sawtooth voltage which is slightly greater in amplitude than its input signal. This output is coupled to the sweep generating circuit through C23.

In explaining the operation of the sweep generating circuit, it was stated that the charge path of the sweep capacitors was through V10B and relay K6 to the voltage source. This statement is not true when considering the operation of the bootstrap amplifier. Since coupling capacitor C23 plays an important part in the operation of the circuit, consider in detail its static condition. The left plate of C23 is connected to the cathode of V10B and will be at plus 150 volts on all but the 5-60 mile range. The right plate is connected to the plate of V11 which is at approximately plus 80 volts during

PR.161

Figure 6-9.—Canopy folded to proper width for making accordion folds into parachute pack. Remove the shot bag from suspension lines and fold the outer edges of the folds in the canopy equally in toward the center to an approximate width of 19 to 20 inches. The canopy is folded lengthwise in thirds, to a point approximately two-thirds up the canopy, measuring from the skirt hem. Place the shot bags on the canopy—one near the point where the folds "break," in order to hold the folded canopy in place.

10992

PR.162

Figure 6-10.—Gaging length of suspension lines required for making first bight. The packer grasps the suspension lines at a point approximately 18 to 24 inches from the connector links in preparation for first bight.

the edge, the fold will be too long. The position of the long bar is important to the neatness of the completed pack. The helper uses his left hand to steady the skirt end at the same time that the first fold is made.

As the canopy is folded on the pack, draw the material of the folds about 2 inches beyond the sides of the pack. This will assure a tight pack when the sides and ends are closed.

Another fold is made and then the packer lifts the pilot chute off the peak and the last fold is cast, turning the peak under approximately 9 inches.

Turn the pack 90 degrees to the left and prepare to compress the pilot chute spring and place the pilot chute directly on top of canopy.

Fake or coil the connector webbing on top of the canopy as the helper prevents the canopy from slipping. Position the pilot chute directly in the center of the pack and compress it while guiding the spring in as straight a pattern as possible.

10995

PR.163

Figure 6-11.—Stowing suspension lines.

Straighten the folds and corners of the canopy. Work the excess fabric back into the center portion of the canopy. Pay particular attention to the corners.

When closing the end flaps, do not pound on the pack or push the canopy out through the end of the container. The end flaps can be worked into position without too much effort by carefully shifting the canopy back and forth.

The opposite end is closed in much the same manner. The helper holds the pack steady while the packer pushes excess canopy fabric back toward the center of the pack and smooths out protruding portions of the canopy folds. The helper then holds the ends of the side flaps down in position while the packer brings up the end flaps.

Hook the pack opening bands and snap the ripcord protector flap in the closed position. Sign the Parachute Record Card and insert it in the outside record card pocket. Insert the emergency signal code in the pocket on the connector strap.

10996

PR.164

Figure 6-12.—Lines stowed, hesitator loops straightened, and pack turned ready to receive canopy.

QUICK-FIT HARNESS ADJUSTMENTS

One of the most important responsibilities of the PR is the training of personnel in the use of parachutes and other survival equipment. All naval aviation personnel should know how to don and adjust the quick-fit parachute harness and how to hook the NC-3 fit parachute to the harness.

The quick-fit harness is designed to be adjusted for body length before the aircraft becomes airborne. The leg straps and chest straps may be adjusted when needed.

Since the harness is designed to serve as a seat or sling to support the wearer during descent, it must be fitted comfortably while the body is in a seated position. Therefore, all quick-fit adjustments are made either in a sitting or simulated sitting position.

To don the harness, slip the arms between the back straps and the chest straps positioned on each side of the harness. Grasp the main sling on both sides and slide it down over the buttocks to form a sling or seat underneath the body. Sit down in a straight chair, or assume a simulated sitting position by bending forward about 45 degrees, bending at the waist and holding the trunk straight. (See fig. 6-27.)

10997

PR.165

Figure 6-13.—Skirt of canopy placed on pack. Bring the skirt in a straight line toward the ripcord end of the pack and place the hem directly over the edge, flush with the wire frame of the pack. Do not permit the free length of suspension lines between the skirt and the last hesitator loop to become entangled in the lines already stowed or to project from the edge of the pack.

10998

PR.166

Figure 6-14.—First fold coming up. The skirt hem is bulky and therefore must be held lightly in place to prevent the disarrangement of the alinement of the skirt hem folds.

The harness should fit the body snugly and comfortably lengthwise when in this position. If it does not, remove the harness and adjust for proper body length. This adjustment is made by moving the shoulder adapters—up to shorten or down to lengthen. After adjustment for length, don harness and reassume the original position for donning. While in this position, adjust the leg and chest straps to a snug comfortable fit.

It will be noted that the properly adjusted harness is extremely uncomfortable when an attempt is made to stand erect. For this reason the harness may be worn loosely for comfort while moving about in the aircraft, and quickly adjusted to the wearer when the need arises. This feature, coupled with the fact that the harness may be worn without the parachute being permanently attached, makes the NC-3 parachute desirable for use in aircraft in which members of the crew are required to move about in the performance of their duties.

It is important to stress that personnel should learn to adjust their harness from the stooped position since rarely will anyone have time to look for a seat in which to adjust his harness when the need arises to use the parachute for an emergency descent. A person should be able to don his harness and chute and prepare to jump from any point in the aircraft.

ATTACHMENT OF THE STANDARD SOFT PACK TO THE NC-3 PARACHUTE CONTAINER

Attachment of the soft pack container to the parachute container must be performed prior to packing the parachute in order to prevent inadvertent stitching of the canopy or suspension lines when making the required hand tackings.

Insure that six 10-inch lengths of type III nylon cord are tied to the standard soft pack outer container as shown in figure 6-28.

Position the standard soft pack outer container on the packing table with the horizontal and vertical strap adapters facing up as shown in figure 6-29.

Insert the combination carrying case and equipment container into the outer container with the shoulder straps facing up and the strap handle positioned at the open end of the outer container. (See fig. 6-30.)

Pull the outer container main panels over the sides of the combination carrying case and equipment container and fasten the vertical strap quick disconnect shackle. Reeve the horizontal and vertical straps snugly together as illustrated in figure 6-31.

Mark the horizontal and vertical straps midway between the adapter and end of the strap as shown in figure 6-32.

Remove the combination carrying case and equipment container from the outer container. Fold the horizontal and vertical straps under at the mark made in the previous paragraph. Tuck the strap ends under the adapters. Tack the folded under strap to the strap located beneath it, passing the cord around the adapter. Use one turn of waxed nylon 6-cord, double. Tie the ends with a surgeon's knot followed by a square knot. (See fig. 6-33.)

Place the standard soft pack outer container on top of the parachute, with the outer container adapters facing the parachute container. Tack the four corners of the standard soft pack outer container to the bottom of the parachute container. Tack the outer container main panel on

10999 8CC01

PR.167

Figure 6-15.—First fold placed immediately behind skirt hem. Bring the first fold up to a position just back of the skirt hem. This compensates for the bulky hem and provides a relatively flat surface on which the other folds can be made.

each side of the vertical strap to the parachute container. Pass all tackings around the parachute container wire frame. Tackings must be made with two turns of waxed nylon 6-cord, double. Tie the ends with a surgeon's knot followed by a square knot as shown in figure 6-34.

Insert the combination carrying case and equipment container into the standard soft pack outer container. Position the parachute container under the riser assembly with the inside facing the packing table and the ripcord pin protector flap facing the canopy as shown in figure 6-35.

Tie the riser assembly quick-connector snaps to the standard soft pack outer container using the six 10-inch lengths of type III nylon cord. Pass the cord through each side of the slot and around the hook on both quick-disconnect snaps. Tie off the ends with a square knot. Tack one turn of waxed nylon 6-cord, single, through each square knot. Tie the ends with a surgeon's knot followed by a square knot. (See fig. 6-36.)

Rotate the parachute container, from the ripcord pin protector flap side over, so that the standard soft pack faces the packing table. The connector links must be positioned on top of the container with the lift webs through the top side flap slots. Tack both sides of the lift webs to the container, passing one turn of waxed size B nylon thread, single, through the webbing and around the container frame. Tie the ends with a surgeon's knot followed by a square knot as shown in figure 6-37.

Remove the combination carrying case and equipment container from the standard soft pack outer container. Pull the parachute container out from under the connector links so that the inside of the parachute container faces the packing table and the ripcord pin protector flap faces the canopy. Fold the side and end flaps under the container and insert the tension hooks into the connector links and the packing table. The assembly is now ready for packing the parachute canopy as illustrated in figure 6-38.

Figure 6-18.—Ready to draw up first side of pack. The packing team holds the pilot chute compressed with their forearms then simultaneously grasps the pilot chute protector flap which is a flap attached to the locking cone side of the pack. As the side is drawn up, keep the fabric from bunching in the center by smoothing down with your free hand between side flap and canopy. Once this side is drawn into position, shift around and pull up the other side while holding the first in place with your arms.

11003 S0011

Figure 16-11.—Sweep amplifying circuits.

static condition. The capacity of C23 is much greater than that of the capacitors used by the sweep generating circuit on any range. Therefore, should the charge on C23 be used as a source of voltage during the time the sweep is being generated, the sweep charging current would have negligible effect on the voltage across C23.

(NOTE: The use of a charged capacitor as a source of voltage for short periods of time has been employed in numerous cases in radar equipment.) Now consider the operation of the sweep generating and bootstrap amplifier circuits. When the pulse from the sweep gate multivibrator cuts off V10A, the sweep capacitors will begin to charge as stated in the previous explanation. However, as the sawtooth is being generated, it is also being fed back to the bootstrap amplifier. This causes the voltage of the right side of C23 to rise. This rise in voltage is coupled to the sweep generating circuit by C23 which causes V10B to be cut off. From this point on to the end of sweep time, the charge on C23 and sawtooth on the plate of V11 will be the source of charging potential for the sweep generating circuit.

The sawtooth on the plate of V11 is of the same amplitude as that appearing on the plate of V10A. This increase results in a constant effective charging potential during sweep time for maximum linearity. Figure 16-12 illustrates graphically the voltage relationship during sweep time.

COMPENSATING GATE GENERATING CIRCUITS

As stated previously, the purpose of the compensating gate circuit is to generate a gating voltage that will cause the indicator's electron beam to be reset at the end of each range sweep, thus insuring that each trace on the indicator will start at the same point. The compensating gate circuit consists of a trigger generator, a multivibrator, a gate clamp, an amplifier, and a driver. It also utilizes two other diode clamp circuits to aid in maintaining proper reference potentials.

Compensating Gate Trigger

The compensating gate trigger V28 (fig. 16-13) is a single-swing blocking oscillator. It is biased beyond cutoff by the voltage divider network consisting of R97 and R98 in its grid circuit. It receives as its input a square wave from the sweep gate circuit. (NOTE: The relationship of this square wave to sweep time is important and is illustrated by waveforms (1) and (2) of figure 16-14.) However, the square wave is differentiated by C45, R97, and R98. The waveform as it appears at the grid of V28 is shown by waveform (3). The negative spike does not affect the operation of the circuit since the stage is cut off when it arrives. However, the positive spike drives the grid above cutoff which starts the oscillator to operating.

Once the grid is driven above cutoff, the oscillator operates as any single-swing blocking oscillator. The circuit has two outputs—(1) a negative spike taken from the remaining transformer secondary winding which is fed to the range marker circuit, and (2) a negative spike developed by the surge of plate current through the plate load resistor. The latter output is

CHAPTER 7

PACKING AND RIGGING THE NB-11 PARACHUTE

The NB-11 personnel parachute assembly is a backtype parachute used with an integrated torso suit harness as part of the ejection seat escape system.

The assembly includes a modified 28-foot diameter, flat, nylon canopy with 28 gores. A fail-safe ballistic spreading gun is used to rapidly deploy the canopy. The canopy is packed in a semirigid contoured container. The riser assembly, which is rigged to the container, is connected to the torso suit harness with quick-release fittings. The integrated torso suit harness combines the aircrewman's parachute harness and lap and shoulder restraint straps. The harness is channeled through the torso suit to retain it in position and to facilitate donning. When aboard the aircraft and seated, the aircrewman connects the quick-release fittings on the parachute riser assembly to the quick-release shoulder fittings on the integrated torso suit. The survival kit is also connected to the integrated suit by means of quick-release fittings.

OPERATION

After ejection, the external pilot parachute is pulled from its pocket and opened, at seat separation, by the static line attached to the ejection seat. At speeds in excess of 120 knots, the external pilot parachute will separate from the container by release of a shear link assembly. At speeds below 120 knots, the external pilot parachute will be retained.

At a preset altitude, the automatic parachute actuator fires. The ripcord pins are removed from the locking cones, allowing the spring opening bands to open the container. The pilot parachute springs from the container and fills with air during this operation. The external pilot parachute release assembly releases the shear link cable when the container opens.

The weight of the aircrewman, falling away from the external pilot parachute (if still attached) and the internal pilot parachute, causes the main canopy to be pulled from the container, followed by the suspension lines. The canopy begins to fill with air during this operation. The connector link ties break as load is applied, allowing the risers to be pulled from the container. The external pilot parachute is used to effect more rapid opening of the parachute, especially at low altitudes or ground level ejection.

Just prior to full suspension line stretch, the spreading gun fires and forces the suspension lines outward at the skirt hem. This aids in rapid opening of the canopy by allowing it to fill with air faster.

If the spreading gun fails to fire, the slugs will separate from the gun assembly at full suspension line stretch, allowing the canopy to open fully.

The aircrewman hangs suspended in his harness from the quick-release shoulder fittings during descent. Upon landing, the canopy and suspension lines can be disengaged from the integrated torso suit by using the quick-release shoulder fittings.

If the aircrewman should have to bail out without using the ejection seat, the internal pilot parachute alone will deploy the main canopy and will disconnect from the external pilot parachute bridle by means of the external pilot parachute override disconnect assembly.

PACKING AND RIGGING THE NB-11

Open the parachute assembly, insuring that the external pilot parachute release assembly releases the swaged ball on the external pilot parachute release cable. USE EXTREME CAUTION AS THIS ASSEMBLY INCORPORATES A BALLISTIC SPREADER GUN. The external pilot parachute is shown in figure 7-1. If the

11017

release assembly fails to release the swaged ball, replace the release assembly.

NOTE: Do not remove the folded canopy or suspension lines from the container.

Carefully raise the folded canopy at the top end of the container, exposing the spreading gun. Open the fasteners on the extractor sleeve and fully insert safety pin into the spreading gun. The safetypin button must be pressed to insert the pin as shown in figure 7-2.

Untie, remove, and retain the 36-inch length of nylon tape securing the canopy peak in position on top of the folded canopy. Remove only the folded canopy from the container. Remove the lower spreading gun firing lanyard from the outboard connector link on the right side of the packing table. Also remove the lower spreading gun firing lanyard from the hesitator loops and retaining bands, and then remove the connector link ties. Remove the external pilot parachute from the elastic stow pocket on the container side flap. Insure that the firing lanyard is not attached to the connector link.

Lay out the canopy and the pilot parachute full length on a packing table as shown in figure 7-3. Rotate the spreading gun so that suspension lines 1 and 28 are facing up and lines 14 and 15 are on the bottom. Separate the folded gores into two groups, counting 14 gores on each side of the spreading gun. Connect the two groups of connector links to their respective tension hooks on the packing table, and complete the parachute assembly inspection in accordance with chapter 4 of this manual.

PR.191

Figure 7-1.—External pilot parachute and deployment bag.

11018

PR.192

Figure 7-2.—Inserting the safety pin into the spreading gun.

SUSPENSION LINE CONTINUITY CHECK WITH SPREADING GUN INSTALLED

Attach the tension strap hook to the loop in the pilot parachute connector cord and tighten.

Suspension lines must be arranged on the connector links in accordance with figure 7-4 and on the spreader gun in accordance with figure 7-5. The spreader gun must be so positioned that suspension lines 1 and 28 face up.

The suspension lines will pass through the corresponding numbered slots in the spreading gun slugs. Insure that loops attached to odd-numbered suspension lines pass through slots in odd-numbered slugs.

Suspension lines must run free from the skirt hem through the corresponding numbered slots in the spreading gun slugs to the connector links without dips or twists.

ATTACHMENT OF SUSPENSION LINE CONNECTOR LINKS TO RISER ASSEMBLY

Lay out risers and cross connector straps on the packing table in a position such that the riser fasteners face the packing table. Remove connector links from tension hooks.

Remove the connector link yoke and plate assembly from each connector link. Insert bottom connector links into the loop at each end of a cross connector strap. Insert bottom connector links in bottom lift webs. Reattach yoke and plate assemblies to the bottom connector links and tighten screws to a torque value of

11019

PR.193

Figure 7-3.—Canopy laid out on packing table.

PR.195

Figure 7-5.—Arrangement of suspension lines on spreader gun.

PR.194

Figure 7-4.—Arrangement of suspension lines on connector links and skirt hem.

20 to 25 inch-pounds. Insure that the knurled portions of the connector link yoke and plate assemblies face up and screwheads face outboard.

Attach the top lift webs and cross connector strap to the top connector links in the same manner. After performing the continuity check, whip and fold the canopy.

STRAIGHTENING CANOPY GORES WITH SPREADING GUN INSTALLED

Insure that the safety pin is installed in the spreading gun and that the spreading gun firing lanyard is detached from the connector link.

Place a shot bag on the right side of the skirt hem. The packer must fold all the gores on the left side as a group, except the bottom gore, over the right side of the packing table. The packer then straightens and smooths the bottom gore, on the left side of the table, throughout its length to the peak. The packer returns the gores above the shot bag on the right side of the packing table to the left side one at a time and straightens and smooths each gore. The folded gores on the helper's side of the table must be straightened and smoothed in the same manner. This procedure is shown in figure 7-6.

INSTALLATION OF SPREADING GUN

Insure that the spreading gun has the safety pin installed. Position the spreading gun between suspension line groups 1 through 14 and 15 through 28 on a whipped and folded canopy so that the upper firing lanyard faces the canopy. Remove the tension strap from the canopy peak. With the use of type III nylon line attached to the upper firing lanyard, pull the upper firing lanyard through the canopy and out the peak.

Untie the type III nylon line from the upper firing lanyard. Route the upper firing lanyard

11020

PR.196

Figure 7-6.—Straightening the canopy.

over the vent lines, through the loop in the pilot parachute connector cord, and under the vent lines. Center the upper firing lanyard plastic sleeve over the indexing line on the firing lanyard. Aline the indexing line on the firing lanyard above the vent lines, as shown in figure 7-7.

Telescope 2 inches of the firing lanyard into itself, forming a 3 (±1/4) - inch loop around the vent lines and connector cord, using a bodkin

11021 02011

PR.197

Figure 7-7.—Routing the upper firing lanyard.

PR.198

Figure 7-8.—Firing lanyard half-hitch and 6-cord tacking.

PR.199

Figure 7-9.—Application of suspension line into slug.

tool, as shown in figure 7-7. Tie a half-hitch around the firing lanyard and telescope the remainder of the end into the firing lanyard. Tack the end inside the firing lanyard with two turns of waxed nylon 6-cord, single. Tie ends with a surgeon's knot followed by a square knot, as shown in figure 7-8.

Aline the top of the spreading gun with the skirt hem and rotate the gun so that the slug labeled "28-27" is facing up. Loosen the screws and plate on "28-27" and place suspension line number 27 and a single length of the attached loop in the closed slot of the slug. Place suspension line 28 in the open slot of the same slug. The numbers on the slugs correspond to the suspension line numbers and loops to be secured in the slug, as shown in figure 7-9.

Insert the plate into the loop and over the suspension lines in the slug. Secure the plate to the slug with the screws provided. Insure that the suspension lines move freely in the slots. Secure the remainder of the suspension lines and loops to the corresponding slugs in the same manner as above. Work from suspension line 26 through 15 and from line 1 through 14. After all the suspension lines are secured, straighten the canopy, as shown in figure 7-10.

STOWAGE OF LOWER FIRING LANYARD IN EXTRACTOR SLEEVE

Do not remove the spreader gun safety pin at any time during this procedure.

Release the fastener holding the stowage sleeve to the extractor sleeve and remove the stowage sleeve from the extractor sleeve. Inspect the lower firing lanyard for proper stowage; if found to be improperly stowed, remove the firing lanyard from the stowage sleeve and proceed as in the following paragraphs.

Cut a 30-inch length of type I nylon line. Do not sear the ends of this line as the seared ends may cause snagging of the firing lanyard. Form a bight twice the length of the stowage sleeve in the lower firing lanyard. Route the type I nylon line through the bight of the firing lanyard and draw only the type I line through the stowage sleeve channel, using a telescoping tool. Slowly remove the type I nylon line from

11022

used to synchronize the compensating gate multivibrator V29 and V30.

Compensating Gate Multivibrator

This multivibrator is used to generate a positive square wave for gating the compensating gate clamp circuit. When the trigger pulse from the trigger generator arrives, V30 is conducting and V29 is cut off. The negative trigger pulse is coupled from the plate of V29 through one of the grid capacitors to the grid of V30. The pulse cuts off V30 and its rise in plate voltage is coupled back to the grid of V29, driving it to saturation. The time V30 remains cut off depends on the values of resistance and capacitance in the grid circuit. Relays K9, K10, and K11 are used to control the RC time in the grid circuit of V30 which, in turn, are controlled by the PRF selection circuit. Thus, the frequency of the multivibrator output is controlled by the sweep gate circuit and the pulse width varies with the PRF of the equipment.

The output of the multivibrator, a positive square wave—the leading edge of which coincides with the end of sweep time—is shown by waveform (5) in figure 16-14. Like the output of the sweep gate multivibrator, this square wave is used as a gating pulse by the compensating gate clamp circuit.

Figure 16-14. —Compensating gate waveforms.

1100

1011 0001

PR.200

Figure 7-10.—Spreading gun installed.

the firing lanyard bight. Use extreme caution when removing the type I line as rapid removal will sever the firing lanyard.

Form and stow a 9-inch bight of firing lanyard in the remaining stowage sleeve channel in the same manner.

Tack the second lanyard bight to the stowage sleeve with 1 turn of waxed size A nylon thread, single. Tie the ends with a surgeon's knot followed by a square knot. Insure that the firing lanyard is not twisted around the 1/2-inch tape. Insert the stowage sleeve into the extractor

11023

sleeve, open end first. Engage the fastener on the stowage sleeve to the fastener on the extractor sleeve. Engage the extractor sleeve fasteners on each side of the safety pin. (See fig. 7-11.)

ATTACHMENT OF THE EXTERNAL PILOT PARACHUTE

Insert the spring and sear attached to the external pilot parachute bridle into the wide end

PR.201

Figure 7-11.—Stowing firing lanyard in stowage sleeve.

11024

of the override disconnect barrel. (See fig. 7-12.)

Push the sear into the barrel, until the sear protrudes from the opposite end. Engage the sear on the internal pilot parachute connector cord with the spring and sear in the barrel and release the tension on the spring and sear. Tack the override disconnect to the external pilot parachute bridle 3 inches above the knot, securing the bridle to the vent line at two places. Use two turns of waxed nylon 6-cord, double, for each tacking. Tie the ends with a surgeon's knot followed by a square knot.

INSTALLATION OF AUTOMATIC ACTUATOR

To install the automatic actuator, rotate the risers over the suspension lines and position the container on the packing table so that the bottom end is toward the canopy and the inside faces up. Insert the power cable through the buttonhole in the top end of the container. Route the end of the arming cable through the housing port located in the right side of the actuator pocket and through the buttonhole located on the right side of the containers, as shown in figure 7-13.

Inspect, arm, and assemble the automatic actuator in accordance with NavAir 13-1-6.2 and chapter 10 of this manual. Record the actuator time delay, installation date, and cartridge expiration date on Parachute Record Card and Parachute History Card.

NOTE: The automatic actuator must be armed with a Mk 4 Mod 0, 0.75-second time delay cartridge or a Mk 4 Mod 1, 0.75-second time delay cartridge.

Install the actuator into the actuator pocket and close the slide fastener. Snap the actuator pocket flap closed.

PR.202

Figure 7-12.—Attachment of external pilot parachute.

PR.203

Figure 7-13.—Installation of automatic actuator.

Install new suspension line retaining bands on the eight retaining band loops. New retaining bands must be installed each time the NB-11 is packed.

ATTACHMENT OF CONTAINER ASSEMBLY TO RISER ASSEMBLY

Remove the tension strap from the canopy peak and remove the tension hooks from the links. Rotate the risers onto the container and secure the riser fasteners to the four inboard container fasteners.

To install the connector link ties, cut two 12-inch lengths of 100-pound nylon cord and sear the ends. Form a 1-inch loop in one end of each line and secure with a bowline knot, followed with an overhand backup knot. (See fig. 7-14.)

Position the connector links side by side so that the top lift webs are on the right and bottom connector links are on the left. Form a noose around the connector links as shown in figure

PR.204

Figure 7-14.—Tying the connector link ties.

11024

7-14. Tighten the noose and tie the free end of the tie cord to the bottom cloth retaining band loop with 3 to 4 half-hitches; trim the excess cord. Secure the connector links on the packer's side and the helper's side in the same manner.

RELEASE ASSEMBLY LANYARD AND RIPCORD ASSEMBLY INSTALLATION

Mark the clamp release lanyard 36 inches from the locking pin end, and fold the top end flap onto the container so that the base plate faces up. Position the large slotted end of the base plate clamp under the screwhead on the base plate. Position the manual ripcord housing and power cable housing under the clamp with the two flat sides together and the other two flat sides against the base plate.

Place the clamp in the clamping groove of the two housings. Position the small slotted end of the base plate clamp over the base plate stud. Insert the release lanyard locking pin into the stud hole, and secure the clamp in place. Insure that the two housings are correctly positioned and securely retained. Safety-tie the locking pin to the stud with one turn of waxed size FF nylon thread, single. Pass the thread through the lanyard knot and tie the ends with a surgeon's knot followed by a square knot. Insert the top ripcord pin through the beveled side of the eye in the power cable.

Route the lanyard over the helper's side of the top end flap "V." Tack the lanyard to the top end flap at the "V" with 1/8-inch slack between the locking pin and the tacking, passing the tacking around the lanyard as shown in figure 7-15. Use one turn of waxed size A nylon thread, single, tying the ends with a surgeon's knot followed by a square knot. Route the lanyard along the inside of the top end flap to the helper's side of the automatic actuator power cable buttonhole.

Tack the lanyard to the upper edge of the container with one turn of waxed size A nylon thread, single, allowing 1/8-inch slack between the tackings. The tacking passes around the lanyard and not through it. (See fig. 7-16.) Tie the ends with a surgeon's knot followed by a square knot.

Reeve the lanyard through the lanyard guide grommet. Locate the 36-inch mark on the lanyard over the bar on the inboard connector link positioned on the helper's side. Secure the lanyard to the connector link bar with a bowline knot. The bowline knot must be positioned as close as possible to the connector link bar. Tie an overhand backup knot in the end of the lanyard cord.

Insert the ripcord housing clip into the riser loop attached to the ripcord handle clip. Using size A nylon thread, single, tack through the loop and hole in the ripcord housing clip. Tie ends with a surgeon's knot followed by a square knot. Insert the ripcord handle in the clip.

ATTACHMENT OF LOWER FIRING LANYARD TO SUSPENSION LINE CONNECTOR LINK

Route the lower firing lanyard at the gun between suspension line 21 and 22. Slide the container towards the canopy and form "S" folds in the suspension lines large enough to allow the loop in the end of the firing lanyard to aline with the connector links. Remove the yoke and plate assembly on the outboard connector link located on the helper's side. Insert the connector link bar through the loop in the lower firing lanyard and reattach the yoke and plate assembly. Tighten the screw to a torque value of 20 to 25 inch-pounds.

STOWAGE OF SUSPENSION LINES

Grasp the suspension lines approximately 16 inches from the connector links and form and stow the first suspension line bight in the hesitator loop farthest from the canopy on the helper's side, as shown in figure 7-17.

The second bight will be stowed in the hesitator loop opposite the first bight on the helper's side. Bights 3 through 8 will be stowed in the same manner as bights 1 and 2. The packer will stow bight 9 in the retaining band next to bight 7. Stow bights 10 through 12 in the same manner as bight 9. There must be 15 (±1/4) inches of line between bights. Packer can stow bight 13 in inboard retaining band across from bight 12. (See fig. 7-18.)

There will be 10 1/2 (± 1 1/2) inches of suspension line between the last stowed bight and the skirt hem.

STOWAGE OF LOWER FIRING LANYARD

Insure that the safety pin is installed in the spreading gun. Form a bight in the lower firing lanyard at the white tape mark on the extractor sleeve. The white tape mark must be

11027

PR.205

Figure 7-15.—Lanyard tacked to top end flap.

22 (± 1/2) inches from the spreading gun. Stow the first firing lanyard bight in the center of suspension line bight number 16, as shown in figure 7-19. Continue stowing the firing lanyard in the suspension line bights 15 through 9 in the same manner as shown in figure 7-19.

Using a 3/8-inch wood or steel rod with a smooth rounded end, tuck a 1/2 (±1/8)-inch bight of firing lanyard into the hesitator loop holding bight 8. Position the bight on top of the suspension lines. Stow bights of firing lanyard in suspension line bights 7 through 4 in the same manner as in the previous step. Position the remaining firing lanyard between the suspension lines and outboard connector link on the helper's side of the container.

STOWAGE OF SPREADING GUN AND CANOPY

Insure that the safety pin is installed in the spreading gun. Do not lift the gun by either the firing lanyard or the skirt hem. Grasp the gun above the safety pin only.

Simultaneously the packer must grasp the skirt hem on the left side with the left hand and the spreading gun with the right hand. The helper

11028

PR.206

Figure 7-16.—Lanyard tacked to upper edge of container.

grasps the skirt hem on the right side. The packer and helper together draw the skirt hem across the container to the top edge and fold it under so the spreading gun is positioned with the firing mechanism facing toward the container bottom. The canopy is lowered into the container with the spreader gun positioned off center to the left, next to the left group of risers, and butted against the top edge of the container. The packer folds the canopy back and removes the spreader gun safety pin. Tuck the canopy into the sides and top corners of the container, and continue folding the canopy, as shown in figure 7-20, up to the third fold.

Cut a 36-inch length of 18-pound nylon tape, MIL-T-5608, and tie an overhand knot in each end of the tape. Insert the tape through the loop on the canopy radial seam, place the tapes across the folded canopy, and continue folding the canopy. Route one end of the 18-pound nylon tape through the vent lines and loop in the upper firing lanyard. Tie the ends of the tape together with a surgeon's knot. (See figure 7-21.)

Check for entanglements in the pilot parachute connector cord. Form a pocket in the top fold of the canopy in line with the second grommet from the top end of the container, and position the pilot parachute override disconnect in the pocket. Position the compressed pilot parachute on top of the override disconnect so that the locking cone is alined with the second grommet from the top end of the container. The pilot parachute temporary locking pin should

11029 11029

PR.207

Figure 7-17.—First and second bight taken in stowing of suspension lines.

extend over the top end flap. Roll the pilot parachute cloth under the outer edge of the crown.

Rotate the container 90° clockwise so the top end of the container is on the packer's side of the packing table. Route the external pilot parachute bridle out the bottom end of the container, to the left of the bottom end flap locking cone. Close the container in the normal manner.

INSERTING THE RIPCORD

The packer will insert the ripcord pin into the beveled side of the power cable eye and into the top end flap locking cone. Replace the temporary locking pins with ripcord pins, working from the packer's side to the helper's side of the container.

Pass the ball end of the shear link through the buttonhole in the bottom end flap of the container, as shown in figure 7-22.

Insert the ball end of the shear link cable firmly into the opening in the external pilot parachute release mechanism. The helper can proceed to tuck the bottom end flap under the side flaps, using long bars inserted into pockets; this will apply tension to the locking lanyard and lock the shear link cable in the release mechanism. The packer and helper must aline the grommets in the side flaps over the locking cone in the bottom end flap. Insert the bottom ripcord into the locking cone and pull on the shear link cable several times to insure that it is properly locked in the release mechanism.

The external pilot parachute bridle must be routed to the left of the bottom end flap locking

11030 DCOIL

PR.208

Figure 7-18.—Suspension lines stowed.

cone. Safety-tie the bottom ripcord pin with one turn of unwaxed size A nylon thread, single. Tie the ends with three to four half-hitches.

NOTE: Do not pass the external pilot parachute bridle under the spring opening bands.

Attach the container spring opening bands to the eyes on the container side flaps and end flaps.

FOLDING AND STOWING THE EXTERNAL PILOT PARACHUTE

Remove dips and twists from the external pilot parachute suspension lines, then whip and fold the pilot parachute canopy in the same manner as the main parachute canopy. (See figure 7-23.)

Fold both sides of the skirt hem together and position above the radial seams. Fold the gores on each side of the radial seams on top of each other above the radial seams. (See fig. 7-24.)

Place a long bar over the folded pilot parachute and fold the peak over the long bar so that the pilot parachute is 1 inch shorter than the deployment bag. (See fig. 7-25.)

Insert the pilot parachute peak into the deployment bag using the long bar, then remove the long bar. Tie each pair of grommets on the deployment bag together with one turn of waxed size A nylon thread, single. Tie the ends with a surgeon's knot followed by a square

PR.209

Figure 7-19.—Stowing the first bight of the lower firing lanyard.

knot. Position the deployment bag so that the static line is on the packer's side of the packing table with the hesitator loops facing up. Form a hook bend in the end of the temporary locking pin. The packer stows a bight of the pilot parachute suspension lines in the hesistator loop farthest from the helper and farthest from the grommets, using the modified temporary locking pin. The remaining suspension lines and four bights of pilot parachute bridle will be stowed in the same manner, as shown in figure 7-26.

Position the external pilot parachute shear link in the center of the elastic stow pocket. Insert the deployment bag into the elastic stow pocket with the suspension lines facing down and the static line facing inboard. Position the deployment bag so that the static line is routed out the center of the stow pocket. Tack both elastic stow pocket flaps to the static line and place the ring on the end of the static line over the arming cable. Route a length of waxed, 6-cord, single, through the adjacent slots in the automatic actuator arming cable fitting. Tie the static line to the arming cable fitting with a surgeon's knot followed by two square knots. Close the lanyard release assembly protector flap. (See fig. 7-27.) Check the flatness of the packed container using a go-no-go gage.

Insure that the fail-safe ballistic spreader gun safety pin has been removed, and account for all packing tools.

The packer must sign off the Parachute Record Card and Parachute History Card.

11032

Compensating Gate Clamp

Before discussing how the compensating gate clamp circuit utilizes the gating pulse, first consider its static state. Referring to figure 16-13, note that R111 and R110 form a voltage divider between minus 300 volts and the cathode of V16 which is approximately positive 6 volts in static condition. The plate of V31A is held slightly positive (approximately 1 volt) with a small current flowing through R102 and V31A.

When the equipment is operating, a sawtooth voltage of approximately 20 volts in amplitude is developed across the sweep driver cathode resistor. This 20-volt increase will increase the charge on C54 and the current through V31A. The voltage to which C54 will charge will be proportional to the amplitude and duration of the sweep sawtooth.

As the sawtooth is terminated, the compensating gate multivibrator produces a positive square wave (discussed previously) which cuts off V31A. This effectively connects the capacitor C54 to the grid of the first compensating gate amplifier. Thus, the voltage across C54 which is proportional to sweep amplitude is used to generate the compensating gate voltage.

A summary of the action of the circuit is as follows:

1. C54 is charged to a voltage that is proportional to the amplitude of the sweep sawtooth.
2. At the end of sweep time the compensating gate circuit is triggered and a square wave gating pulse is generated.
3. This square wave is used to disconnect V31A from the circuit.
4. The voltage across C54 is now applied to the grid of the first amplifier.
5. At the end of the gating pulse, V31A conducts and the circuit is ready for its next sweep.

Study the waveforms in figure 16-14 carefully and insure that the time relationship of each waveform is understood.

Compensating Gate Amplifier

The compensating gate amplifier consists of two voltage amplifiers and a cathode follower. (See fig. 16-15.) Their function is to amplify the compensating gate pulse to the proper level to drive the compensating gate driver. The amplifier is similar to the sweep amplifier discussed in the previous section and therefore is discussed only briefly.

CHAPTER 8

PACKING AND RIGGING THE MARTIN-BAKER PARACHUTE

The Martin-Baker parachute is designed to be used with the Martin-Baker ejection system. The complete ejection system consists of an ejection seat, ejection gun, drogue gun, two drogue parachutes, time release mechanism, and personnel parachute and harness assembly.

The system is designed to provide safe escape at all altitudes and speeds, and after ejection, to automatically extract the personnel parachute and lift the occupant from the ejection seat.

Ejection at ground level during takeoff or landing when the airspeed is 100 knots or over is both safe and practicable because of the high ejection velocity of the ejection gun and the rapid extraction of the personnel parachute.

When ejection is made above 10,000 feet, a barostatic control prevents separation of the pilot and seat during the descent to 10,000 feet. The occupant is supplied with oxygen during the descent, and his drop is controlled by the stabilizer drogue.

Normal ejection is accomplished by pulling a face (blind) curtain. A secondary handle is located on the forward part of the seat bucket and is used if normal ejection cannot be effected. Either action causes the seat to be propelled upward by three successively fired cartridges operating in a telescoping ejection gun composed of three cylinders.

After ejection, the following operations take place:

1. The ejection seat drogue gun fires a piston which deploys the controller drogue parachute.
2. The controller drogue parachute, in turn, deploys the stabilizer drogue parachute. The stabilizer drogue parachute remains attached to the seat by a scissor shackle.
3. The scissor shackle is released at a preset altitude and safe "G" level by the operation of the time release mechanism. The aircrewmen separates from the seat during this operation.
4. When the stabilizer drogue parachute releases from the seat, it pulls the withdrawal line assembly from the container assembly. As the withdrawal line reaches full stretch, the ripcord locking pins are removed from the locking cones, permitting the grommets, locking cones, and end tabs to disengage.
5. The container spring opening bands pull the end side flaps apart, allowing the pilot parachute to spring from the container and fill with air.

If the ejection seat time release mechanism fails to operate, the aircrewman can manually disengage himself from the seat by pulling the emergency harness release handle. This procedure is also followed in crash rescue operations. When manual disengagement is necessary, the guillotine assembly will cut the withdrawal line (if the slide disconnect pin is not used), securing the drogue parachute to the pilot parachute. The slide disconnect pin, if used, replaces action of the guillotine assembly. The manual ripcord handle is then pulled, deploying the pilot parachute which deploys the canopy. The canopy fills with air and the aircrewman hangs suspended in his harness.

Although personnel of the AME rating are responsible for the removal and installation of the seat and its components, the PR is responsible for packing and rigging both the drogue chutes and the personnel parachute.

Personnel parachute packs of various shapes are used with Martin-Baker parachute canopies. The type of pack used depends on the design requirements of the seat and aircraft concerned. Two of these containers are the horseshoe and the envelope. The most unusual of these types is the horseshoe. Coverage in this section is limited to the integrated horseshoe type.

The Martin-Baker horseshoe pack is a back type, secured to the seat by two restraining straps. It is shaped like a horseshoe to allow

U 11038

the shoulder straps to pass under the arch of the horseshoe into the top lock of the inertia reel while leaving the canopy free for clean extraction through the opening in the top of the pack.

Differences occur in packing of the various types of Martin-Baker parachutes. Therefore, before attempting to pack one of another configuration, be sure to consult NavAir 13-1-6.2, covering the parachute and seat involved.

DUPLEX DROGUE PARACHUTES

The drogue parachute assembly (fig. 8-1) is composed of two parachutes—a 22-inch diameter controller drogue (small controller) and a 5-foot diameter stabilizer drogue (main stabilizer).

This assembly stabilizes and decelerates the seat with a minimum of altitude loss, and positions the seat in a convenient attitude for occupant separation. Upon actuation of the time release mechanism, the main drogue parachute extracts the occupant's personnel parachute from its container, and releases the occupant's face curtain restraints and personnel parachute slide disconnect static cable anchorage, if applicable.

When the drogue gun is fired, the projectile (connected to the controller drogue withdrawal line) first pulls the drogue container spring pin, releasing the four flaps. The pull of the projectile through the withdrawal line pulls the drogue from the top of the container. The pull of the deployed controller drogue extracts the stabilizer drogue from its container by the withdrawal line connected to the apex. After deployment, the stabilizer drogue stabilizes and decelerates the seat and occupant with a minimum of altitude loss and positions the seat into a convenient attitude for occupant separation.

The two drogue parachutes are fabricated of a cotton material and stowed in the headrest structure at the top of the seat. The controller drogue is packed on top of the stabilizer with a protective cloth sleeve between the two. The packed controller is attached to the controller drogue withdrawal line, and covered by four cloth flaps which are secured by a pin.

The face blind is stowed in a separate compartment at the front of the drogue parachutes container. The face blind handle cross tube is retained at each end by a spring-loaded pin which engages in a hole in the side of the container. The face blind straps extend aft through a channel-shaped housing within the container on each side and terminate in lugs which are retained by the link line pins. The face blind firing cable passes aft through the container and emerges between the flaps, together with a secondary firing cable.

PR.218

Figure 8-1.—Martin-Baker drogue parachutes.

REMOVAL AND INSTALLATION

In order to assure safe operation of the seat, it is essential that the drogue parachutes be properly packed, and that the lines are correctly routed.

The drogue parachutes should normally be inspected and repacked at intervals of 182 days

(maximum), unless required more frequently by unusual circumstances. This work should be done only by personnel qualified in parachute handling.

It is not necessary to remove the drogue parachutes to the parachute loft for repacking. It is recommended that this work be done indoors with a clean surface available on which the parts may be laid, but it may be performed on the aircraft if necessary.

The following safety precautions must be observed:

1. If seat is not installed in the aircraft, check that the ejection gun is not with the seat and that the drogue gun is either unloaded (barrel removed) or safetied (safety pin in hole).

2. If the seat is installed in the aircraft, check that the safety pins are installed in the ejection gun sear and in the drogue gun safety pin hole.

The life of the face blind is 36 months after installation in the aircraft. The expiration date is stamped or stenciled on the face blind. The face blind should be replaced with a new one when the life period has expired. Expiration dates and replacements must be recorded in the aircraft logbook.

Removal of Face Curtain (Blind)

Retaining the safety pin in the ejection gun sear, push the sear forward and remove two firing cable eyes from the hook of the sear. This step is not necessary if the seat is not mounted on the ejection gun.

Remove the safety pin from the face curtain and stow in the clip on the seat pan.

Pull on the striped face curtain handle to extend the face curtain, then pull the firing cable forward through the hole in the container.

Pull the link line pins out of the fittings at the sides of the container to free the lugs at the ends of the face curtain restraining straps. The face curtain may now be removed from the seat. This step is necessary only if it is desired to remove the face curtain from the seat.

Removal of Drogue Parachutes

Disconnect controller drogue withdrawal line from the drogue gun piston by removing the nut and bolt. Temporarily replace the bolt and nut in the small shackle.

Break and remove the safe-tie thread on the flap securing pin.

Pull the flap securing pin out of the flap pocket and out of the wire loop on the flap. The pin will also be pulled out of the shackle safe-tie loop. This loop of nylon line may be reinstalled later if not damaged.

Lift up the scissor and shackle to a vertical position.

Placing the secondary firing cable to one side, fold back the four flaps and pull out the controller drogue by means of its withdrawal line.

Pull out the protective sleeve and remove the stabilizer drogue by pulling on the withdrawal line.

Note that the drogue shackle is still held in the scissor and retains the stabilizer drogue suspension lines. It is not necessary to break this connection; but if it is desired to remove the drogue parachutes from the seat, proceed as follows:

1. Unscrew the link line connector, if the personnel parachute is installed.

2. Operate the time release mechanism by pulling the trip rod sear. Keep hands away from descending plungers to avoid injury. After operation, replace the trip rod sear fully home in the time release mechanism.

3. Open the scissor and remove the shackle. The link line will also be removed, as it is attached to the shackle.

Examine the drogue parachutes, suspension lines, withdrawal lines, shackle attachments, etc., for evidences of possible deterioration. Take corrective action if necessary.

Clean the inside of the drogue parachute container.

Packing Stabilizer Drogue Parachute

Open the four flaps. Pull up the protective sleeve and roll it down so that it does not obstruct the packing.

If the drogue shackle has been removed from the scissor, proceed as follows:

1. Place the shackle bolt within the jaws and close the scissor. The link line should be forward and the eye of the stabilizer drogue suspension line should be aft.

2. Cock the time release mechanism. The shackle will then be retained in the scissor.

Holding the stabilizer drogue, extend the suspension lines from the shackle and straighten them out, so that they are not twisted or tangled.

Pair off the 24 suspension lines and fold the skirt into 6 double folds. (See fig. 8-2.)

11040

PR.219

Figure 8-2.—Pairing suspension lines.

PR.220

Figure 8-3.—Martin-Baker drogue chute packing.

Holding the folds as shown in view (D) of figure 8-2, stow the suspension lines as follows:

1. Lead the sleeve protected portion from the shackle down the right aft corner of the container.

2. Stow the remainder of the suspension lines in the bottom of the container by looping them from side to side.

Stow the stabilizer drogue on top of the suspension lines. Insert the skirt first and pack the parachute in accordion fashion well down into the container. The apex remains on top. (See fig. 8-3 (A).)

Unroll the protective sleeve and pack it down into the container to cover the stabilizer drogue. At the same time, bring the withdrawal line out at the right aft corner of the container, together with the suspension (shackle) line.

Packing Controller Drogue Parachute

Holding the controller drogue, extend the suspension lines and the stabilizer drogue withdrawal line and straighten them out, so that they are not twisted or tangled.

Pair off the 10 suspension lines and fold the skirt into 3 single folds.

Holding the folds, stow the lines as follows:

1. Folding the withdrawal line into about 7 folds, place it in the front part of the container.

2. Loop the suspension lines over the remainder of the protective sleeve.

Fold the apex of the controller drogue on top of the skirt and stow in the container with the apex toward the left rear corner of the container toward the drogue gun, then pack it down. (See fig. 8-3 (B).)

The controller drogue withdrawal line must emerge from the left rear corner of the container toward the drogue gun. Loop the line behind the parachute so that 3 inches of line are exposed beyond the flap securing pin.

11041

Closing Flaps and Stowing Face Blind

If the face blind has been removed from the seat, proceed as follows:

1. Bring the face blind up to the headrest with the firing cable on top. (See fig. 8-4.)

2. Push the strap lugs back through the housings on each side and locate the lugs in the fittings for the link line pins, being sure the straps are not twisted.

3. Insert the link line pins into fittings at sides of the headrest, making sure that they pass through the lugs of the face curtain restraint straps and the lugs of the parachute restraint straps, if installed.

4. Mate or connect the link line connector, if removed, and personnel parachute is installed.

Pass the face curtain firing cable through the hole in the center of the container and lead aft. During this operation, push the packed parachute down with the finger to assure that there is no entanglement.

PR.221

Figure 8-4.—Stowing face curtain (blind).

Fold the undersides of the face curtain to the width of the container mouth.

Fold under the stitched aft end of the face curtain and insert it into the container.

Close the right, left, rear, and front flaps—in that order. Be sure that the wire loop on the right flap extends up through the grommets on the other three flaps. During this process make certain that the two firing cables pass under the front flap and over the rear flap.

Fold the scissor and shackle forward and down on top of the flaps.

Insert the points of the flap securing pin (on withdrawal line) through the wire loop of the flaps, then through the shackle safe-tie loop, and finally into the pocket on the front flap.

NOTE: If it should be necessary to replace the shackle safe-tie, use single nylon 6-cord Spec. MIL-C-7807 Type I or II, and tie the loop with a square knot. The loop must pass under the flap securing pin (not through it) between the wire loop and the pocket. The scissor and shackle must be free to lift up when the pin is pulled out by the withdrawal line.

Safe-tie the flap securing pin with a single loop of 6-cord nylon, through the eye of the pin and through the loop on the flap pocket; then tie with a double square knot. The two safety ties, which hold the flap securing pin and the drogue shackle in place must be replaced every 91 days. This can be done with the parachute in place.

Stow the remainder of the face curtain into the container and, using the thumbs, pack firmly into the sides.

Push the cross tube of the handle into the container, first one side and then the other, retracting the pins in turn. Make sure that the pins extend into the fittings on each side.

Install the face blind firing handle safety pin.

Connect the controller drogue withdrawal line to the drogue gun piston with the bolt and nut of the small shackle.

WARNING: It is essential for safe operation of the seat that the withdrawal line be routed over the link line and not under it, so that the withdrawal line is free to extract the controller drogue without entanglement.

MAIN PARACHUTE CANOPY

An Irvin 24-foot diameter flat nylon canopy with 24 gores is used with the Martin-Baker ejection seat. As stated earler, the canopy is

11042

The positive gate on the grid of V32 is amplified and inverted, and fed to the grid of V33. The gate is again amplified and inverted and appears as a positive gate on the grid of the cathode follower V34. The diode V31B is employed as a clamper to insure that each gate starts from the same static potential. The grid of the cathode follower is connected to a negative 85 volts, permitting an input signal of considerable amplitude without distortion. It should be noted that inverse feedback from the cathode of the driver to the cathode of the first amplifier is used to improve the shape of the compensating gate output.

Compensating Gate Driver

The driver V35 is identical to the sweep driver V16. Its output is a square wave of the same area as the sweep waveform. Although the compensating gate is of the same polarity as the sweep voltage, it is inverted since it appears at the opposite end of the primary winding of T2. Thus, the compensating gate is combined with the range sweep sawtooth voltage as shown in figure 16-16.

INTENSITY GATE CIRCUIT

The purpose of the intensity gate circuit is to provide a means of unblanking and blanking the indicator at the proper time. However, before discussing the intensity gate circuits, consider the circuits that provide it with a trigger or gating pulse. When the equipment is using a delay, the intensity gate circuit is triggered by the output of the sweep gate multivibrator. However, this pulse is not usable without prior amplification. This is accomplished by the sweep gate amplifier and the sweep gate cathode follower.

Sweep Gate Amplifier and Cathode Follower

The sweep gate amplifier V27 is conducting during static condition. (See fig. 16-7.) A negative square wave is applied to its control grid during sweep time, cutting it off. This produces a positive-going square wave which is direct-coupled to the grid of the sweep gate cathode follower V26. Its output, taken from the cathode, is fed to pin 4 of relay K15B. Thus, when the equipment is using a delayed operation, the intensity gating circuit is controlled by a positive square wave of the same time relationship as the range sweep sawtooth.

Figure 16-16.—Range sweep sawtooth and compensating gate voltage waveform

Intensity Gate Output

The intensity gate output V25 (fig. 16-17) is a cathode follower whose input comes from either the sweep gate output (just discussed) or the rangemarker gate circuit, depending on the type of operation employed. In either case the operation of the intensity gate stage is identical. Its input is a positive-going square wave, beginning and ending with sweep time, which causes V25 to conduct heavily. The increased current flow develops a positive square wave at the output, which is coupled to the intensity gate clamp circuit.

Figure 16-17.—Intensity gate circuit and waveforms.

packed in a soft, horseshoe or envelope type container. The integrated torso harness combines the aircrewman's parachute harness and shoulder restraint straps. The harness is channeled through the torso suit to retain it in position and to facilitate donning.

When aboard the aircraft and seated, the aircrewman connects the quick-release fittings (Koch) on the parachute riser assembly to the quick-release shoulder fittings on the integrated torso suit. The survival kit is also connected to the integrated torso suit by means of quick-release fittings (Rocket Jet).

The parachute and lift web assembly normally remain installed in the aircraft, except when removal for packing of the chute or servicing of the seat is required.

This section describes the procedure for packing the personnel parachute into the horseshoe pack. Before beginning the packing, check that the pack zippers are open, that pack opening bands are released, and that loose threads are removed. Parachutes in service are required to be repacked to coincide with the applicable aircraft inspection cycles specified in NavAir Inst. 4700.2.

Packing and Rigging

Lay the parachute on the table with the canopy assembly laid out its full length. Locate the canopy gore with the nameplate and place it uppermost in the center of the table. Separate the suspension lines into two equal groups, counting 12 lines on each side of the nameplate gore as shown in figure 8-5.

The connector links will have the snap fasteners down and be in position to attach to the tensioning device. (See fig. 8-6.)

Locate suspension lines No. 1 and No. 24. Follow lines down to the connector links (these lines must be on the inside of the upper links). Place the links on the tensioning device.

PR.222

Figure 8-5.—Arrangement of suspension lines.

Grasp the left and right paired groups of lines and follow them up to the skirt of the parachute to assure that there are no twists. If twists are found, pull the pack and lift web assembly through the lines until straight. (See fig. 8-7.) Pull the tensioning device strap up tight.

Check to insure that the lines at the apex are even and that the vent is straight with approximately the same length of line on each side of the loop in the connector cord.

Folding the Canopy

Untie the antisquid lines at the connector links and whip and fold the canopy in the same manner as described in chapter 6 of this manual for packing the NC-3 parachute. Fold each group of 12 gores in thirds, forming an S fold. (See fig. 8-8.) Place a shot bag on the folds near the skirt.

Extend the S fold on each side, holding the folded width to a minimum by keeping the edges of the folds parallel up to the point where the folds run out (about 4 feet from the apex). Place another shot bag across the canopy to hold the upper part of the folds in place while continuing the packing process. (See fig. 8-9.) Remove the tensioning device.

Unhook the vent of the canopy and slide the skirt of the canopy toward the connector links approximately 14 inches. At the same time, draw both sets of suspension lines out to the side, forming an arrow. (See fig. 8-10.) It should be noted that the antisquid lines remain in the center of the table. Retie the antisquid lines to the connector links.

Antisquid Lines

The antisquid lines are incorporated to promote parachute opening at low speeds by preventing squidding of the canopy and thereby improving the low altitude capabilities of the system.

Squidding of the canopy is the tendency of the skirt of the canopy to partially close, due to the weight of the ejection seat and the pilot working against the force of the fully opened 5-foot controller drogue. The two 400-pound rayon cord lines are braided and coreless and are cut 26 feet in length. Both of these lines should be marked 12 inches from each end. To obtain

11043

PR.223

Figure 8-6.—Layout of webs for packing.

accuracy in measurement, each line should be tensioned to a load of 5 pounds when being cut. Dip the free ends of the lines in a hot melted mixture of 50 percent paraffin and 50 percent beeswax, thereby preventing the ends of the lines from fraying. The antisquid lines are passed up through the center of the canopy. They are secured to the bight of the parachute withdrawal line and the suspension lines at the apex of the parachute with two turns and three half hitches. (See fig. 8-11 (A).) Be sure that the first knot is tied on the 12-inch mark. Whip the free end of the line with 3/4-inch pressure sensitive filament adhesive tape. Secure the other end of the antisquid line to the top connector link, passing the line under the first three suspension lines and parting the suspension lines so that the antisquid lines have three suspension lines on each side. Secure the line with two turns and three half hitches, insuring that the first knot is tied on the 12-inch mark. (See fig. 8-11 (B).) Whip the free ends with pressure sensitive filament adhesive tape.

Stowing the Suspension Lines

Before stowing the suspension lines, completely unzip and open the parachute pack and check that the pack opening bands are released. The antisquid line is not stowed with the suspension lines until the suspension lines are stowed in loop No. 8. Begin stowing the lines in the loop nearest the connector link. Pull the bight through the first two loops so that the loops of the suspension lines will be toward the inside leg of the pack when it is folded back over for closing. Bights will extend a maximum of 1/2-inch beyond hesitator loop. Then route the lines to the bottom center of the leg and take a bight through loop No. 3. Continue stowing the lines by pulling a bight alternately from one side to the other until loop No. 8 is reached. Stow the antisquid line with the suspension lines in loop No. 8. (See fig. 8-12.) Continue stowing the suspension lines through all the loops in the leg. Figure 8-13 illustrates the lines as stowed in one leg of the Martin-Baker pack. The helper will repeat the same process for the suspension lines in opposite leg.

After stowing the lines in both legs, bring the two groups of lines together at the arch of the pack. If the lengths of the two sets of lines are uneven to the skirt, place the junction off-center toward the side which is shorter, and stow the remainder of the suspension lines in the loops which are outside the legs. (See fig. 8-14.)

On one side, close the protective flap over hesitator loops 1 and 2, pass a length of FF nylon thread through each of the loops on the flap

011044

PR.224

Figure 8-7.—Separating the two groups of suspension lines.

and through the corresponding loops on the pack, and tie with a surgeon's knot and a square knot. Tie the flap, covering loops 3 through 13 in the same manner, then repeat the entire process for the opposite leg of the pack. (See fig. 8-15.)

Remove the lower shot bag and bring the canopy over the pack with the skirt touching the arch of the horseshoe.

Stowing Lower Canopy

Grasp all gores except Nos. 1 and 13 near center. While retaining the double fold in the other gores, pull this half of the skirt down to a position about 4 inches from the bottom of the pack leg as illustrated in figure 8-16.

Grasp the top part of the double fold at the side and pull the skirt down to the bottom of the pack leg in a telescopic fashion so as to finish in a taper. (See fig. 8-17.)

Close the slide fastener at the bottom, tucking the parachute in carefully to make sure that it is not caught in the teeth of the slide fastener. Pull the protective flap up between the fabric of the canopy and the slide fastener and close about 6 inches of the leg of the pack. Repeat the same procedure for the opposite leg of the pack. (See fig. 8-18.) Make sure that the legs of the pack are filled out firmly.

4011045

PR.225

Figure 8-8.—Folding each group of gores into double folds.

Inserting the Pack Stiffener

Insert the pack stiffener into the pocket provided, and secure into place by tying the nylon laces which are attached to the pack. The excess length of these cords may be tied back out of the way by tying a double bow knot in the ends. (See fig. 8-19.)

Stowing Upper Canopy

While keeping the double folds of the canopy intact, grasp the canopy and begin making accordion folds across the upper section of the pack. Make the folds 3 to 4 inches wider than the pack in the manner shown in figure 8-20. When the entire canopy is folded into the top of the pack, there will be approximately four folds with the apex in the center facing the packer. The suspension lines which emerge from the apex should be folded across the vent and brought back to the helper. Lead the pilot chute connector cord and the withdrawal line to the ripcord side of the parachute. Sign and insert the packing record card in the inside pocket, which is located on the inside front of the pack.

Closing Side and Top Flaps

Tuck the upper part of the canopy into the pack. First, bring the inner back flap over the parachute, next the front, and then the back flap. Then close the slide fasteners on each leg.

NOTE: When closing the zippers, it is important to make sure that the protective webbing is in position on the inside of the fastener so that the canopy does not become enmeshed in the teeth of the zipper.

Place the pack on the packing stand. This will assist in keeping the pack in position while tucking in the flaps and making the final steps to complete the packing operation. (See fig. 8-21.)

Tuck the canopy into the pack, making sure that the withdrawal line emerges from the pack on the ripcord side.

Pull the inner back flap over on top of the folded canopy, and pull the front flap which carries the locking cones over it. Place the ejector board so that it lies on top of both front and back flaps. (See fig. 8-22.)

Pull the main flap forward, fit the grommets over the cones, and insert the temporary locking pins into the cones. Tuck in the left side corner of the front inner flap, lift the withdrawal line, and place the small triangular flap on top of the inner flap. Replace the corner of the main flap on top of the withdrawal line. Bring up the flap opposite the ripcord, remove the temporary locking pin, and place the end tab

11046

PR.226

Figure 8-9.—Extending the folds of the canopy.

over the cone. Replace the temporary locking pins.

Place the ripcord pins (attached to the withdrawal line) in position alongside the locking cones. Open the slide fastener on the left side about 5 inches down the side of the pack and insert all excess length of the withdrawal line. Close the slide fastener.

Folding and Inserting Pilot Chute

Check the pilot chute suspension lines for dips and twists, then lay the canopy on the table with the suspension lines up. Let the folds of the canopy fall in over the ribs of the spring, forming a square. Place the connector cord and folded suspension lines diagonally across the canopy of the pilot chute. (See fig. 8-23.)

Grasp the two ribs of the pilot chute lying parallel to the connector cord. Close these ribs in together, then pull up the other two ribs in the same manner. Hold the folded canopy and ribs in one hand, pull the canopy out between the ribs into four triangular folds, and insert into the pack on top of the ejector board. Fold the remainder of the connector cord and tuck in under the ejector board.

Insert the rear ripcord pin through the eye on the end of the ripcord cable. Remove the temporary locking pin from the rear locking cone (the cone nearest the end of the ripcord cable), and place the cable securing plate in position over the locking cone. Insert the rear ripcord pin through the hole in the rear locking cone. (See fig. 8-24.)

Completing the Pack

Safety tie the right-hand locking pin in the same manner as described in chapter 6 for the NC-3, using size A thread. Fold the ripcord pin protector flap back on top of the locking cones, then fold the withdrawal line in a loop on top of the flap. Fold over the top outer flap, and secure the two snap fasteners. Hook the pack opening elastics.

Make sure that ripcord handle is installed correctly in the spring clip with handle facing outboard of the lift web. NOTE: The ripcord for the integrated Martin-Baker parachute differs from ripcords for the conventional Navy parachutes in that an eye is swaged to the end of the cable which would normally have the ripcord pins attached. The cable housing also

11047

PR.227
Figure 8-10.—Suspension lines out to the side, forming an arrow.

PR.228
Figure 8-11.—Installation of personnel parachute antisquid lines.

differs from other housings in that it is smaller in diameter, has a protective covering of a green plastic type substance, and has a cable securing plate attached to the free end.

The ripcord handle end of the cable housing is attached to the left-hand lift web at a point near the rocket jet fitting and then reeved through a nylon canvas channel sewn to the edge of the lift web. As it emerges from the channel, the end of the cable housing is a free end until the cable securing plate is set over the cones and held in place by the locking pins.

Sign the outside packing card, when the pack is complete.

PERSONAL SURVIVAL KIT

Survival equipment kits are now being tested which will tend to standardize survival kits for all types of aircraft. These kits are the rigid seat survival kit (such as the one described in chapter 15 of this training manual for use in aircraft utilizing ejection seats) and the "soft pack" kits for use in nonejection type aircraft. Although in the future no "soft pack" kits are to be used with ejection seats, the one described in this chapter has been used until recently

C001 11048

PR.229

Figure 8-12.—Antisquid line stowed with suspension lines in loop No. 8.

with certain of the Martin-Baker ejection seats. Before attempting any maintenance work on these survival kits be sure to consult the Maintenance Instructions Manual covering the aircraft and seat concerned.

The "soft kit" consists of two assemblies: the seat pan assembly and the survival kit assembly.

SEAT PAN ASSEMBLY

The seat pan assembly is designed to provide an emergency oxygen breathing supply to the pilot during ejection at high altitudes and, when the pilot is using a full pressure suit, to maintain pressurization corresponding to an altitude of 35,500 feet. The system is automatically actuated upon ejection or may be

11049

PR.230

Figure 8-13.—Suspension lines stowed in one leg.

manually actuated by the pilot. A gage installed at the upper left front of the seat indicates the oxygen supply pressure. This system also furnishes pressurization and oxygen breathing supply in the event of a failure of either system in the aircraft. The seat pan assembly incorporates provisions for the attachment of the survival kit, as well as the shock and comfort pads.

SURVIVAL KIT ASSEMBLY

The survival kit consists of survival equipment in a special container assembly. The equipment kit contains survival gear to sustain the pilot in the case of an emergency. This gear includes the following:

LR-1 pararaft.
Equipment container.
Water storage bag.
Appropriate pilot's emergency beacon.
Nylon cord (50 feet).
Dye marker.
Desalter kit.
Solar still.
Signal mirror.
Bailing sponge.
Poncho.
Rations.
Ointment.
Sea anchor.
Inflation cylinder.
High-speed container.

The LR-1 pararaft and CO_2 bottle fill the aft section of the equipment kit and are connected

12011
11050

PR.231

Figure 8-14.—Suspension lines placed in loops outside the legs.

by a line zipper ring of the survival kit. The container assembly flaps are folded inward to protect the pararaft and CO_2 bottle and are secured by a ripcord assembly. The ripcord assembly pins secure the outer flap of the container on locking cones. A lanyard from the ripcord assembly to the CO_2 bottle manifold pulls the bottle and pararaft from the container when the ripcord is pulled to open the container assembly. A release cord on the CO_2 bottle must be pulled to inflate the raft. The survival kit is strapped to the seat pan and is stowed in the seat bucket beneath the seat pan.

NOTE: The contents of the survival kit as listed above are considered as typical of a survival kit and substitutions may be made as directed by local authority.

A typical personal survival kit is shown in figure 8-25.

MARTIN-BAKER SAFE-TIES

Table 8-1 shows the recommended safe-ties for the Martin-Baker parachute.

11059

CHAPTER 9

AUTOMATIC PARACHUTE ACTUATORS

MASTER SPECIALTIES PARACHUTE ACTUATOR

The automatic actuator currently used by the Navy in personnel parachute assemblies is a barometrically controlled, pyrotechnic device. The actuator is designed to open a parachute at a preset altitude of 14,000 (±500) feet above mean sea level (MSL), for all parachutes except those used in the T2A, T2B, and A5 series aircraft. The T2A, T2B, and A5 will be set at 10,000 (±500) feet above MSL. Figure 9-1 shows a cutaway view of the Master Specialties actuator.

OPERATION

When an aircrewman bails out at an altitude above that for which the actuator is set to open the parachute, the arming pin is pulled. This pin locks the actuator firing mechanism while installed. When the arming pin is withdrawn, the assembly will fire at or below the preset altitude for the actuator. The sear and aneroid mechanism locks the actuator. As the aircrewman free-falls, increasing air pressure causes the aneroid to contract. As the operating altitude is reached, the aneroid contracts enough to remove the sear from the firing hammerlock. The hammer's firing pin strikes the time delay cartridge which fires 3/4, 2, or 3 seconds after the hammer strikes, depending on the type of cartridge used. A piston is forced out of the barrel and pulls the power cable, which is attached to the parachute locking pins. The locking pins are pulled and the standard parachute opening sequence begins.

PREPARATION FOR USE

Upon removal of the actuator from the shipping carton, the exterior parts of the unit should be inspected for damage during shipping and storage. An inspection should be made for corrosion, dirt, dents, and cracks. If any damage or discrepancy is found, a tag must be affixed to the actuator, stating that the actuator is not to be used. Remove this tag only after correction has been made.

Loading

To load the actuator, proceed as follows:

Remove the screw (3) and washer (4) from the cover assembly (fig. 9-2). Slide the receiver assembly from the cover assembly and check the position of the hammer assembly. If the hammer assembly is not in the position shown in figure 9-3 (A), completely separate the barrel assembly from the receiver assembly and allow the hammer assembly and lock to drop into the armed and cocked position.

Insert the pin of the arming knob assembly (24, fig. 9-2) through retainers (34). The pin must pass through the holes in the lock (28).

With the hammer assembly secured in the armed position, reassemble the barrel assembly to the receiver assembly.

WARNING: Engage the forked end of the longest spring of the barrel assembly with the pin on the hammer assembly so that hand pressure is needed to press the barrel into the recess of the receiver assembly. If the spring is inadvertently positioned under the hammer assembly pin, the unit will not operate.

Use only the proper length barrel assembly. Barrels are not interchangeable between models. For example, a 1000C barrel will not properly fit a 1000D receiver.

Insert a cartridge in the barrel (fig. 9-4) and press the barrel into the recess of the receiver assembly. Slide the receiver assembly into the cover assembly, exercising care that the base of the housing assembly is properly alined with the barrel assembly and the cover assembly. NOTE: The cartridge service life is 5 years from the date of manufacture or 18 months after opening of the original package, whichever occurs first.

11080

PR.243

Figure 9-1.—Master Specialties actuator (cutaway view).

WARNING: Exercise extreme caution after the cartridge has been inserted in the barrel. Do not allow either end of the cover assembly to be pointed toward the face as flame and smoke may result in injury. Another reason for extreme caution is the possibility that the piston of the actuator may become a projectile if the cartridge accidentally fires.

Install the washer and screw in the cover assembly.

Figure 9-2. —Master Specialties parachute actuator.

Installation

Connect the swaged fittings at the end of the power cable assembly to the parachute ripcord.

Attach the parachute actuator to the parachute pack in accordance with the instructions contained in the applicable Aviation Clothing and Survival Equipment Bulletin, or NavAir 13-1-6.2.

ADJUSTING THE ANEROID.—There may be a number of Master Specialties Model 1000C and Model 1000D actuators in service with an altitude setting of 10,000 feet, mean sea level. If a walk-in type chamber is available, the altitude setting of these actuators may be changed to the correct altitude setting of 14,000 feet ±500 feet by the procedures discussed in the following paragraphs. The altitude setting of 14,000 ±500 feet is designed to give flying personnel greater protection while operating over high mountainous terrain.

Remove the receiver assembly from the cover assembly of the actuator. Then remove the barrel and piston assembly from the receiver assembly and remove the explosive cartridge. Do not remove the arming pin. Install a dummy cartridge in the barrel and replace the barrel

11062

Intensity Gate Clamp

The intensity gate clamp V18B is a negative clamper. It clamps the positive portion of the square wave from V25 at the zero reference voltage. This effectively provides a negative square wave for blanking the indicator's sweep when there is no sweep voltage fed to the indicator (flyback). Waveform (3) illustrates the waveform fed to the indicator.

RADAR TRANSMITTERS

The transmitter functions to provide RF energy, often at extremely high power, for short intervals of time. The science of radar requires that the frequency of this energy be in the microwave region. The high-power oscillator that produces the RF carrier is usually a magnetron.

MODULATING THE MAGNETRON

The modulator for the magnetron serves a double purpose—it determines the waveform of the output pulse, and it stores energy between pulses and releases it through the magnetron during the pulse.

The basic circuit for a magnetron modulator is shown in figure 16-18. In this circuit the storage element is charged through the charging impedance Z_{ch} and the load. It is discharged through the load when the switch is closed. On examining this circuit, you can see that closing the switch also completes a circuit containing the power source and Z_{ch}. This has little consequence, however, since the switch is closed for only a microsecond or so at a time and Z_{ch} is large enough to prevent any damage. It is well to become familiar with the components of some of the modulator circuit elements which are shown as blocks in this circuit. In the modulator, the source from which the storage element is charged may be either a d-c voltage or an a-c voltage. The magnetron requires a voltage of 10 to 15 kilovolts or higher for proper operation. In some types of equipment a transformer is used between the storage element and the magnetron to step up the voltage, while in many others a direct connection is made between the storage element and the magnetron. Actual charging circuits are discussed in a later section dealing with line-pulsing modulators. In these circuits the charging impedance may be a high resistance or a high inductance, or both. Its purpose is to control the charging time for the storage element and to prevent short circuiting of the source during the pulse.

Figure 16-18.—Basic circuit for storage and release of energy in a modulator.

SWITCHING DEVICES

Switches for controlling the discharge time of pulse-forming networks may be of various types. Three types that will be discussed in this chapter are the ROTARY SPARK GAP, GAS DIODE, and THYRATRONS.

Rotary spark gaps are generally not used in aviation equipment because they are instable, must be enclosed in a pressurized chamber, and different repetition rates are difficult to obtain.

Gas diodes are used in some high-powered modulators. Figure 16-19 illustrates a gas diode type switch in which two cold cathode gas diodes are used. Some equipments use more than two of this type diode. These tubes are

Figure 16-19.—Gas diode switch.

1103

PR. 245

Figure 9-3. —Firing mechanism.

and piston in the receiver assembly. Place a hose clamp around the barrel and tighten it until the barrel lies flush with the receiver, as shown in figure 9-5. Prior to removing the aneroid sealing compound, it is advisable at this point to perform an actuator operating altitude check. It is possible that the actuator was previously adjusted to 14,000 ± 500 feet, but not properly marked. If the actuator operating altitude test confirms a 10,000-foot setting, remove the sealing compound from the end of the aneroid assembly using a pointed instrument; this will expose the aneroid adjusting screw.

Take the receiver assembly into a low pressure chamber, evacuate to 14,000 feet, and level off. Remove the arming pin from the assembly. Loosen the small Bristol locking set-screw on the side of the aneroid adjusting screw (fig. 9-6). slowly turn the aneroid adjusting screw clockwise until the aneroid assembly is retracted far enough to release the lock from the sear and permit the hammer assembly to strike the dummy cartridge. Tighten the locking setscrew at this setting (NOTE: Never allow the unit to fire unless it is loaded with a dummy test cartridge.) Remove the hose clamp and place the hammer assembly in the armed and cocked position and insert the arming pin through the retaining holes in the receiver. Place the hose clamp around the barrel and tighten until the barrel lies flush with the receiver.

Evacuate the chamber to 16,000 feet and remove the pin. Descend in altitude at a rate of approximately 200 feet per second. Record the altitude at which the aneroid releases the lock and permits the hammer to strike the dummy cartridge. Repeat the steps above; both runs must be 14,000 ± 500 feet. Make certain the locking screw as shown in figure 9-6 is set. Fill the aneroid adjusting screw with auto body filler, and paint the aneroid with red lacquer and stencil 14,000 FEET on the end of the aneroid cover on the receiver.

Parachutes having automatic actuators installed with the 14,000-foot setting will have a notation recorded on the Parachute History Card, and the Parachute Record Card.

NOTE: Actuators 1000A and 1000B are not to be reset, but are to be removed from service.

PR. 246

Figure 9-4. —Installing cartridge in barrel.

INSPECTION.—Any automatic actuator in service must be inspected each time its parachute assembly is repacked. Careful attention and close supervision are required when work is performed on an actuator. Operation of the actuator is a critical function of a parachute assembly and any carelessness or misunderstanding in inspection or assembly can easily result in failure of an assembly. Supervisors must impress upon both riggers and quality assurance inspectors the importance of careful work. After any modification, the actuator must be reinspected.

To inspect the automatic actuator, proceed as follows:

1. Remove the cartridge from the actuator. If the actuator has been fired, it must be scrapped. Check the nameplate on the housing or receiver. The actuator must be a 1000 series Model C (Mod), Model D, Model F, or Model 153-100. Models A and B must be turned in to Supply.

2. Inspect the hammer and lock. If the sear is in the full forward position locking the hammer, the receiver has a defective aneroid.

PR. 248

Figure 9-6. —Locking setscrew.

3. Check the receiver body of the actuator for dents, corrosion, and distortion. Inspect the interior parts for freedom of movement and corrosion.

4. Inspect the cover assembly as follows:

a. Check the metal housing for bends, dents, sharp edges, and corrosion.

b. Inspect the power cable tube for dents, security of the power cable locking ring, and presence of plug in the end.

PR. 247

Figure 9-5. —Master Specialties actuator barrel assembly clamp.

11064

c. Examine the power cable housing and cable for signs of corrosion, breaks, permanent bends, and security of swaged fittings.

d. Check the swaged ball on the end of the power cable. The ball must be inside the main housing and not in the power cable tube.

5. Inspect the barrel and piston assembly for proper installation. All springs must curve away from the barrel and the smallest spring will be nearest the barrel.

6. Examine the safety wire on the barrel for proper size and type (0.032 inch, soft copper wire), installation, and security.

TROUBLESHOOTING.—Table 9-1 lists the most common troubles, along with the probable causes and remedies.

CARTRIDGE ACTUATED WEBBING CUTTER

The webbing cutter is a factory-loaded expendable unit powered by a small blank cartridge. The unit weighs 16 ounces and is 2 1/2 inches wide, 1 1/4 inches thick, and 1 1/2 inches high.

The purpose of the webbing cutter is to sever the right-hand riser of nonintergrated parachute assemblies after parachute descent and land or water impact. Cutting of the riser results in the collapsing of personal parachute, preventing the the pilot or crew-member from being dragged by an inflated parachute. The device cuts only one riser and does not eliminate the need for immediate parachute removal in order to prevent being pulled under the water by the sinking parachute. The unit is not reusable once it has been fired.

Operation

Removal of the safety cover exposes a T handle lanyard as shown in figure 9-7 (A) and (B). Pulling the lanyard outward, from the assembly, fires the cartridge mechanically. When the lanyard is pulled, a spring-loaded firing pin is released and strikes the primer, firing the cartridge. (See fig. 9-7 (B).) The gas resulting from the cartridge firing passes through a port in the cutter body and contacts the top of the knife assembly. The knife assembly is held in position by a shearpin. When the pressure of the gas is completely developed, the pin shears and the knife assembly is propelled by the gas pressure, cutting the webbing slot and impacting the hardened base plate as shown in figure 9-7 (C). The gases generated by cartridge firing are contained by O-rings, and the knife assembly is a captive mechanism when the base plate is secured by the positioning screw.

Installation

Modification of the parachute assembly is not required. It is mandatory that the webbing cutter be mounted by a single hinging action to the right riser webbing below the parachute harness adjustable strap adapter as shown in figure 9-8. CAUTION: Do not install the webbing cutter to the left riser because the ripcord pocket which is sewn to the left riser would restrict separation after the webbing is severed. The installation of the webbing cutter is to be accomplished without removing the safety cover. Prior to installation, determine the service life of the webbing cutter (5 years from date of manufacture which is stamped on the container, or not more than 1 year after the sealed metal container is opened, whichever occurs first). Stamp the expiration date (that is, the date the cutter is to be removed from service in accordance with the above criteria) on the body of the cutter device between the webbing slot and the safety cover.

Remove the positioning screw shown in figure 9-7 (C). This will allow the base plate to swing open. Insert the right riser assembly into the slot with the webbing cutter base plate next to the wearer's body. The cutter is to be installed so that the safety cover is removed by a motion away from the body. Close the base plate and replace the positioning screw tightly. Loop the tiedown cord through and around the loop in the right riser for the back strap. Tie both ends securely with a square knot. Fastening of the tiedown prevents the cutter from sliding during routine handling and operation and firmly anchors the cutter during parachute deployment. Installation instructions are embossed on the back of the cutter base plate.

Operation Procedures

Using the right hand, remove the slide cover by a pulling motion away from the body. A quick visual inspection can be made by observing the direction of the arrow mounted on the cover. (See fig. 9-7 (B).)

Removal of the safety cover exposes the firing lanyard. Grasp the lanyard and pull away from the body. Pulling directly forward is preferred, although the cutter will actuate when the lanyard is pulled in any direction away from the

11065

40011

Table 9-1.—Troubleshooting Chart for Master Specialties Actuator.

Trouble	Probable Cause	Remedy
Sear engages lock at altitude less than 14,000 feet.	Aneroid assembly leaks.	Return to Supply.
	Aneroid assembly bent.	Return to Supply.
	Receiver housing bent.	Return to Supply.
Power cable or arming pin cable stuck in housing assembly.	Housing assembly damaged.	Return to Supply.
	Cable assembly defective.	Return to Supply.
Cartridge will not fit in barrel.	Wrong size cartridge.	Use recommended cartridge.
	Obstruction in barrel.	Remove obstruction, clean barrel.
Barrel assembly cannot be seated in receiver assembly.	Hammer assembly has not been pinned in armed position and allows firing pin to restrict seating of parts.	Insert arming pin through lock.
Receiver assembly will not fit in cover assembly.	Cover assembly dented or damaged.	Return unit to Supply.

body. Operation instructions are embossed on the safety cover.

Inspection

1. Insure that the positioning screw is tightly secured and the back plate is engaged.

2. Inspect the tiedown cord for security to the harness.

3. Check the direction for removal of safety cover away from the body. Gently slide the safety cover back a quarter of the way and observe that the lanyard and T handle are in place in accordance with figure 9-7 (A). The lanyard will not be visible if the cutter has been fired because the lanyard and the cover cannot be replaced on a fired unit.

4. Determine the service life of the webbing cutter.

CHAPTER 10

PARACHUTE MAINTENANCE AND REPAIRS

Materials used in parachute construction are of the very best grade obtainable. All of these materials—the fabric, webbings, cords, tapes, hardware, and fasteners—are manufactured in accordance with strict government specifications.

A specification is a document intended primarily for use in procurement, which clearly and accurately describes the essential and technical requirements for items, materials, or services, including the procedures by which it will be determined that the requirements have been met.

In the case of the Armed Forces, specifications are necessary to insure that the item procured meets all the requirements for which the government is paying and that the item will perform all the necessary functions.

As each item is procured under this program, it is assigned a Military (MIL) Specification number. The MIL specification numbers listed in this chapter are now in effect. However, specifications are revised from time to time, and specification numbers are often changed, canceled, or superseded. The Index, List of Military Specifications and Standards, NA 00-25-544, lists all specifications in effect and those recently canceled. This index is reissued periodically under the supervision of the Naval Air Systems Command and is available in your technical library.

As a PR, you must not tolerate the use of substitutes or substandard materials in the fabrication or repair of survival equipment. A knowledge of specifications and tensile strengths will better equip you to design local projects which must meet specified tensil strength requirements.

The prime authority for all parachute construction, component replacement, and perplexing repairs will be the applicable drawing of the parachute concerned. The drawing numbers of parachute assemblies and particular components may be found in the Master Drawing Index.

Activities servicing parachutes should maintain a file of current parachute drawings, and review any extensive rework for compliance with the drawing.

Parachute assemblies requiring maintenance, repair, modifications or repack will be assigned to the lowest maintenance level capable of performing the work, in accordance with NavAir Instruction 4700.2.

TYPES OF FABRIC MATERIALS

NYLON PERSONNEL PARACHUTE CLOTH

Nylon parachute cloth used in the construction of personnel parachutes is made in accordance with Specification MIL-C-7020. This cloth is neutral in color unless otherwise specified, and is used in constructing the gores and panels of the parachute canopy. The specification states that the maximum weight cannot be more than 1.1 ounces per square yard. The breaking strength in minimum pounds per inch of width is 42 pounds. The minimum tear resistance is 5 pounds for both the warp and filler thread. The air permeability in cubic feet per minute per square foot of cloth is 80 to 120.

NYLON CORD

Nylon cord used for suspension lines for pilot chutes and parachutes is made in accordance with Specification MIL-C-5040. Type I cord, 100 pounds breaking strength, is used for the lines of Martin-Baker pilot chutes. Type III, 550 pounds breaking strength, is used for constructing the suspension lines of the canopies of service personnel parachutes.

83 11069

NYLON REINFORCING TAPE

Nylon reinforcing tape is made in accordance with Specification MIL-T-5038. Reinforcing tape comes in many widths and styles. Some of the uses for this tape are parachute container reinforcements, edgings, hesitator loops, and general strengthening of stress areas.

Type II tape is three-fourths of an inch wide and has a minimum breaking strength of 400 pounds. Type IV tape comes in both 1-inch and 1 1/2-inch widths. The 1-inch width has a minimum breaking strength of 1,000 pounds, and is used to reinforce end flaps. The breaking strength of 1 1/2-inch tape is 1,500 pounds. This tape is used to construct hesitator loops and to house phenol fiber stiffeners. Type VI tape is three-fourths of an inch wide and has a breaking strength of 425 pounds.

NYLON WEBBING

Nylon webbing is made in accordance with Specification MIL-W-4088. Type VI nylon webbing is used for the construction of harness keepers, carrying handles on the NC-3 parachute, and reinforcement of corners and chaffing webbing. It has a breaking strength of 1,800 pounds.

Another type of webbing is type VIII. This is used to manufacture the cross-connector straps on the NC-3 parachute. It has a tensile strength of 3,600 pounds.

Type XIII soft textile nylon webbing is used for constructing parachute harness. This webbing has a breaking strength of 6,000 pounds and is olive drab in color. The width of this webbing is 1 23/32 ± 1/16 inch.

Type XVII 1-inch nylon webbing is used for the construction of end tabs. Its breaking strength is 2,400 pounds.

TUBULAR NYLON WEBBING

Nylon tubular webbing is made in accordance with Specification MIL-W-5625. Nylon tubular webbing is neutral in color and is used in reinforcement of the parachute canopies. Nylon tubular webbing is also used in making the pilot chute connector cords. The 1/2-inch tubular webbing has a breaking strength of 1,000 pounds and is used for the pilot chute connector cord on the NB-6, NB-7, NB-7E, NB-8, NB-9, NB-10, NB-11, NC-3, NS-3, and LW-3B parachutes. All MBEU parachutes use 1,500 pound tubular nylon webbing, 9/16-inch wide for making their pilot chute connector cords.

The 1-inch nylon tubular webbing has a breaking strength of 3,000 pounds and is used for the vent reinforcement. The nylon warp and cotton filler webbing is also 1-inch wide and has a breaking strength of 525 pounds. It is used to reinforce the skirt hem.

FABRIC CONTAMINATION INSPECTION AND REMOVAL

Parachute assemblies must be carefully inspected for evidence of contamination. The various types of contamination are acid, alkaline, salt water, fresh water, perspiration, mildew and fungus, fire fighting agents, mud, dirt, and petroleum.

ACID AND ALKALINE

Parachute assemblies suspected of acid or alkaline contamination must be tested with pH test paper. A pH reading of 5.0 to 9.0 is in the safe zone. Readings below 5.0 indicate excess acidity, and readings above 9.0 indicate excess alkalinity.

To test for excess acidity or alkalinity dampen the suspected area with distilled water. NOTE: Handle test paper by one end or edges only to prevent obtaining a false reading.

Place a piece of full range test paper (0.0 to 14.0 pH) on dampened area. A color change will indicate the approximate pH and which specific shortrange test paper to use. Place a piece of shortrange test paper indicated in the above test on the dampened area. The color change indicates the pH factor of the affected area. By matching the test strip with the applicable range color chart supplied with the pH indicator kit, acid or alkaline strength can be determined.

If contamination is found, care must be used to prevent contact between the contaminated area and other portions of the assembly, as this could spread the damage.

If acid contamination is found, the affected parachute assembly must be forwarded to supply for screening.

If alkaline contamination is found, rinse with cool, fresh water until a safe pH reading is attained. Carefully inspect for deteriorated portions, repair or replace any affected areas.

11070

SALT WATER CONTAMINATION

Parachutes that have been contaminated by salt water must be cleaned, inspected, and treated as soon as possible after contamination. Any portion of a parachute assembly which has been immersed in salt water for a period of more than 24 hours must be turned into supply for screening. Any portion of a parachute assembly which has been contaminated by salt water and cannot be cleaned within 36 hours must be turned into supply for screening. Clean any parachute assembly contaminated by salt water as described later in this chapter.

PERSPIRATION CONTAMINATION

Any parachute assembly which is stained with perspiration must be cleaned as described later in this chapter. After cleaning, the fabric affected must be closely inspected to insure that deterioration has not taken place. Scrap or repair any damaged portion of the parachute assembly.

FRESH WATER CONTAMINATION

Any parachute that has been contaminated by fresh water must be dried as soon as possible. The assembly must then be inspected for signs of stains by oil, hydraulic fluid, mud, etc. Such stains must be removed by cleaning as described later in this chapter.

MILDEW AND FUNGUS CONTAMINATION

If mildew or fungus is present on a parachute assembly, wash the affected area with a mild soap and water solution. Rinse the affected area thoroughly with clean, fresh water and hang the assembly by vent lines in a wet locker to dry.

FIREFIGHTING AGENTS CONTAMINATION

If a parachute assembly is contaminated with firefighting agents, forward to supply for screening.

PETROLEUM PRODUCTS CONTAMINATION

Oil, grease, hydraulic fluid, and other petroleum stains must be removed by repeated applications of a mild soap and water solution. Each application must be followed by a rinse in clean, fresh water. Hang the assembly by vent lines in a wet locker to dry.

CLEANING PARACHUTE ASSEMBLIES

Cleaning of parachute assemblies should be held to a minimum and done only when necessary to avoid malfunction or deterioration.

Do not scrub fabric with any cleaning implement or against itself, do not brush fabric. Do not pick at or try to break off dried or caked mud. Wrap all metal fittings in heavy flannel cloth.

Hang the parachute assembly by vent lines and thoroughly shake to remove all sand, dust, and mud. If the assembly is wet, immerse it in clean, fresh water not over 120° F. Gently move the parts by hand until all air pockets are removed. Agitate by hand until water flows through and around the fabric. MACHINE AGITATION MUST NOT BE USED.

After 5 to 10 minutes, lift the assembly from the tub and allow to drain as completely as possible. Drain and rinse the tub and refill with water; repeat the 5 to 10 minute wash twice.

If the parachute has dried before the first rinse is performed, the first rinse must be preceded by a 2- to 3-hour soaking in a tub filled with clean, cool, fresh water. If a large tub is not available, hang the assembly by the canopy vent lines and spray clean using clean, fresh water not over 120° F.

Do not use a forced-heat dryer. Do not wring water from the canopy.

Place the cleaned parachute assembly into a low speed dryer and spin dry. If a low-speed dryer is not available, hang the parachute assembly by vent lines in a wet locker only until dry. When the assembly is completely dry, remove the flannel cloth from the metal fittings.

If the parachute assembly has stains which cannot be removed by the procedure described in the foregoing paragraphs, it must be forwarded to a depot-level maintenance activity for additional cleaning. Attach a report of the nature and location of stains.

STENCILING PARACHUTE ASSEMBLIES

Parachute assemblies are marked by the manufacturer in accordance with the general

110741

specifications for parachutes. When a parachute is placed in service from stores, the month/year of opening the manufacturer's individual shipping container must be stenciled on the canopy nameplate gore. Letters are 1/2 inch high and made with blue parachute marking fluid (MIL-I-6903). The term "date placed into service" followed by month/year notation must be placed directly below the nameplate.

When a replacement parachute harness is installed, the date, preceded by the letter "R," must be stenciled in the center of the horizontal back strap in letters 1/2 inch high.

Service life of integrated torso suit harness is the same as for parachute assemblies. The start-of-service date must be stenciled in the center of the lap belt strap outer surface. Use black washproof ink (TT-I-542).

Use an appropriate size adjustable metal stencil for all markings on parachute assemblies. Join each letter properly in the grooves provided. When the stencils are joined, aline the letters or figures in order to prevent a wavering line. Use the end plates provided in each kit, which offer the necessary margin to prevent smearing the marking fluid off the ends. Hold each letter down tightly as the fluid is applied with a dampened brush. Do not attempt to stencil with a wet brush as the fluid will run off in all directions. Wipe the back of the stencil clean with a dry cloth between each operation. Before storing, clean the adjustable stencils in a safe cleaning solvent.

STITCHES, SEAMS, AND STITCHINGS

Federal Standard No. 751 is the official standard specification used in the manufacture and repair of parachutes, survival equipment, and other items which require the use of stitches, seams, or stitchings. The following information is taken from this specification.

CLASSIFICATION OF STITCHES, SEAMS, AND STITCHINGS

As a prerequisite to an understanding of stitches, seams, and stitchings, a clear understanding of their classification and the terms employed in their use is essential.

Stitches

A stitch is one unit of conformation of thread resulting from repeatedly passing a strand or strands and/or loops of thread into or through a material at uniformly spaced intervals to form a series of stitches.

Stitches are divided into six classes which are identified by the first digit of three-digit numerals. Each class is divided into several types which are identified by the second and third digit. These classes are as follows:

100—Chain stitch
200—Hand stitch
300—Lock stitch
400—Multithread chain stitch (double locked stitch)
500—Overedge stitch
600—Flat seam stitch

STITCH CLASS 100.—This class of stitch is formed with one or more needle threads and has for its general characteristic interlooping. A loop or loops of thread or threads must be passed through the material and secured by interlooping with succeeding loop or loops to form a stitch, as shown in figure 10-1.

STITCH CLASS 100.—This class of stitch is formed with one or more needle threads and has for its general characteristic interlooping. A loop or loops of thread or threads must be passed through the material and secured by interlooping with succeeding loop or loops to form a stitch, as shown in figure 10-1.

STITCH CLASS 200.—This class of stitch is formed by hand with one or more needle threads. Each thread passes through the material as a single line of thread, and the stitch is secured by the single line of thread passing in and out of the material or interlooping of the threads with themselves. When more than one thread is used, the threads pass through the same

PR.251

Figure 10-1.—Stitch type 101. This type of stitch is formed with one needle thread which is passed through the material and interlooped with itself on the undersurface of the material.

11072

connected in series and an equal resistance is connected in parallel with each so that the high voltage will divide equally across each tube. This division prevents the voltage across either tube from becoming high enough to cause the tube to conduct.

As illustrated figure 16-19, the trigger pulse is applied across one diode and causes it to conduct. This conduction causes the triggered diode to appear as a closed switch which connects the full high voltage across the other diode and causes it to conduct. The conduction of this tube closes the network circuit. This circuit remains closed until the storage network discharges to the point where the diodes de-ionize. At this time the storage network begins to recharge.

The thyratron is the more common switching device utilized in modulators. It is operated at cutoff until a positive trigger pulse is applied to the grid. The tube then conducts until the network circuit becomes discharged to the point that the thyratron de-ionizes and the grid regains control. The most common thyratron of this type is the HYDROGEN THYRATRON. While the gas diodes require an extremely high trigger voltage, the hydrogen thyratron requires a much lower voltage, approximately 30 to 100 volts. The normal life of this type of thyratron is expected to be about 900 hours; tube life is influenced by repetition rate and not pulse widths, providing the widths do not exceed 5 microseconds. The two advantages of the thyratron switching system are the accuracy of the firing time and the fact that the thyratron is not affected by the impedance of the trigger source.

PULSE-FORMING NETWORKS

The pulse-forming network consists of a series of coils and capacitors in an arrangement like that shown in figure 16-20. There are other arrangements for the elements in the PFN, but the arrangement shown is the most common. Most pulse-forming networks have a CHARGING CHOKE in series with the input. The choke is series resonant with the line and isolates the power supply from the switching device during discharge time. The LC constants in the network are carefully selected to provide a pulse of the proper shape and duration. The coils and capacitors must be rated to withstand the high voltages and currents they encounter in building up the high-powered pulse.

The PFN and charging choke are designed so that their combined impedance matches the output load as nearly as possible when the network is switched. The output line therefore appears as an infinitely long transmission line when the switch is closed. This reduces reflections in the charging circuit during the discharge interval. During the charging time, however, when the switch is open, the network is resonant. It can be shown that when a voltage is suddenly applied to an inductance and capacitance in series, the voltage at the resonant frequency of the circuit oscillates in such a manner as to give a sine wave, the amplitude of which is almost twice the applied voltage.

Figure 16-20. —Schematic diagram of a typical pulse-forming network and charging choke.

1104
6011

perforations in the material, as illustrated in figure 10-2.

STITCH CLASS 300.—This class of stitch is formed with two or more groups of threads and has for a general characteristic the interlacing of the two groups. Loops of the first group of threads are passed through the material where they are secured by the thread or threads of the second group to form a stitch. This is the most common type of stitch in use in repair and maintenance of parachutes and other survival equipment. It is made by machine and is illustrated in figure 10-3.

STITCH CLASS 400.—This class of stitch is formed with two or more groups of threads and has for a general characteristic the interlacing and interlooping of the loops of the two groups. Loops of the first group of threads are passed through the material and are secured by interlacing and interlooping with loops of the second group to form a stitch.

PR.252

Figure 10-2.—Stitch type 201. This type of stitch is formed with two needle threads (A) and (A') passed through the material in the same perforations from opposite directions without interlacing or interlooping.

PR.253

Figure 10-3.—Stitch type 301. This type of stitch is made with two threads: one needle thread (A) and one bobbin thread (B). One loop of thread A is passed through the material and interlaced with thread B. Thread A is pulled back so that the interlacing is midway between the surfaces of the material being sewn.

STITCH CLASS 500.—This class of stitch is formed with one or more groups of thread, and loops from at least one group of thread are passed around the edge of the material. Loops of one group are passed through the material and are secured by interlooping with themselves before succeeding loops are passed through the material, or secured by interlooping with loops of one or more interlooped groups of threads before succeeding loops of the first group are passed through again.

STITCH CLASS 600.—This class of stitch is formed with two or more groups of threads, and two or more groups cover the raw edges of both surfaces of the material. Loops of the first group of threads are passed through loops of the third group already cast on the surface of the material and then through the material where they are interlooped with loops of the second group on the underside of the material. The one exception to this procedure is stitch type 601. In this type only two groups of thread are used and the function of the third group is performed by the threads of the first group.

Seams

A seam is a joint consisting of a sequence of stitches uniting two or more pieces of material and is used for assembling parts in the production of sewn items. Seams are divided into four classes:

SS—Superposed seam (Superimposed)
LS—Lapped seam
BB—Bound seam (Binding)
FS—Flat seam

Seams are further subdivided into types, designated by a system of lowercase letters which indicate the type of the class. These types run consecutively through the alphabet; however, since there are many variations of seams and only 26 letters in the alphabet, multiple lowercase letters must also be used; for example, a, b, c, aa, ab, etc.

Most seam types can be produced using either one row or multiple rows of stitches. The number of rows of stitches is indicated by an arabic numeral preceded by a dash; thus, the complete symbol for a simple superposed seam formed with standard stitch type 301 and one row of stitches is specified 301-SSa-1.

SEAM CLASS SS.—In this class of seam the plies of material are superposed and sewn with one or more rows of stitches.

11073

SEAM CLASS BS.—This class of seam is formed by folding a binding strip over the edge of one or more plies of fabric and seaming the strip to the material with one or more rows of stitches.

SEAM CLASS LS.—In this class of seam the plies of material are lapped and seamed with one or more rows of stitches.

SEAM CLASS FS.—This class of seam is formed by seaming the abutted edges of the material together in such a manner that the stitches extend across and cover or tend to cover the edges of the plies joined.

Typical examples of these seams are illustrated in figure 10-4. A careful study of these examples will give the reader an idea of the basic seams and stitchings used in the repair of survival equipment. However, when a specific seam is called for in a drawing or a specification, reference should be made to Federal Standard 751 for the specifications for the seam or stitching to be used.

Stitchings

Stitching consists of a sequence of stitches for finishing an edge or for ornamental purposes (or both) in preparing parts for assembly. Stitchings are divided into two classes as follows:

OS—Ornamental.

EF—Edge finishing.

These stitchings are illustrated in figure 10-5. Note the difference between these stitchings and the previously mentioned seams. These stitchings are used as finishing touches to a product.

PR.254

Figure 10-4.—Classes of seams.

PR.255

Figure 10-5.—Stitching class OS and EF.

STITCHING CLASS OS.—In this class of stitching a series of stitches are embodied in a material either in a straight line, a curve, or following a design, for ornamental purposes.

STITCHING CLASS EF.—In this class of stitching edge, finishing is accomplished by either (1) stitching a series of stitches at or over the edge of a material (the edge may or may not be folded as specified), or (2) the edge of the material is folded and stitched to the body of the material with a series of stitches.

CHARACTERISTIC OF SEAMS AND STITCHINGS

A properly constructed seam or stitching must have strength, elasticity, durability, security, and a neat appearance. These characteristics must be balanced with the properties of the material to be joined to form the optimum seam. The end use of the item will govern the relative importance of these characteristics, and the selection of the seam or stitching type should be based upon these considerations.

Strength

The strength of a seam or stitching should equal that of the material it joins in order to have balanced construction that will withstand the forces encountered in the use of the item of which the seam is a part. The elements affecting the strength of a seam or stitching are as follows:

Stitch type.
Thread strength.
Stitches per inch.
Thread tension.
Seam or stitching type.
Seam efficiency of the material.

11074

Elasticity

The elasticity of a seam or stitching should be slightly greater than that of the material which it joins, so that the material will support its share of the forces encountered in the end use of the sewn item. The elasticity of a seam or stitching depends upon the following:

Stitch type.
Thread elasticity.

Durability

The durability of a seam or stitching depends largely upon its strength and the relation between the elasticity of the seam and the elasticity of the material. However, in the less elastic, tightly woven, dense materials there is a tendency for the plies to "work" or slide on each other. To form a durable seam or stitching in such materials, the thread size must be judiciously chosen and the stitches well set to the material (without undue tension which will unbalance the elasticity and cause puckering) to minimize abrasion and wear by contact with outside agencies.

Security

The security of a seam or stitching depends chiefly upon the stitch type and its susceptibility to become unraveled. The stitch must be well set to the material to prevent snagging which can cause rupture of the thread and unraveling of certain stitch types.

Appearance

The appearance of a seam or stitching generally is governed by the proper relationship between the size and type of thread, the length of stitch or number of stitches per inch, and the texture and weight of the fabric. In addition to this relationship, the technique and skill of the sewing machine operator also governs the appearance of the seams and stitchings.

Some of the factors which adversely affect the appearance of seams and stitchings are listed below.

Defects in stitchings:
- Loose stitches.
- Poorly formed stitches.
- Crowded stitches.
- Tight stitches.
- Crooked stitches.
- Skipped stitches.

Defects in seams and stitching:
- Puckers.
- Twists.
- Pleats.
- Raised seams (run-offs).
- Felled seams (raw edges exposed).

PATCHING THE PARACHUTE CANOPY

A canopy is considered beyond repair if one or both of the following conditions exist: One or more complete gores are torn or there are holes larger than 8-inches long in four or more sections. If damaged beyond repair, the canopy should be forwarded to a supply activity for screening. Any section with holes, tears, or cuts larger than 8 inches must be replaced in accordance with drawings and specifications.

Only two single patches or one double patch may be installed on a single section. If additional patches are required, replace the section. Any hole, cut, or tear 1 inch square or less may be patched with a single patch. A severe separation or a separation with broken threads must be patched using a single reinforcement patch. Holes larger than 1 inch must be repaired using a double patch, one on the inside and one on the outside of the section. The patch on the inside must be applied first.

If a thread separation is not severe and no threads are broken, the thread can be pressed into place using a soft brush or a pencil eraser. Do not brush the damaged area in the wrong direction as this will cause the separation to increase.

SINGLE PATCHING

Single patches are sewn to the inside of a canopy. A hole or tear less than 1 inch square or a thread separation must be repaired with a single patch.

Salvaged or overaged material must not be used to repair a canopy; all repair materials must have a shelf life of 2 years from date of manufacture.

If a cut or tear is even and no canopy material is missing, baseball-stitch the patch or tear. Lock the first and last stitch. Figure 10-6 shows the method of baseball stitching.

If a cut, tear, or hole has canopy material missing, trim the edges and cut a filler patch the same size and shape as the cut, tear, or hole.

11075

PR.256

Figure 10-6.—Baseball stitching a tear.

Baseball stitch the filler patch in the hole, locking the first and last stitch. (See fig. 10-7.)

To obtain the measurements of the patching material, outline a damaged area using a soft lead pencil. Outline a minimum margin of one inch around a 1- to 3-inch hole; 1 1/2 inches around a 3- to 6-inch hole; and 2 inches around a 6- to 8-inch hole. If possible, anchor the patch to at least one seam or hem.

Place a piece of new material over the outlined area so that the weave of new material matches the weave of the canopy. Cut the patch 1 inch larger than the outlined area.

Place the damaged area with the inside of the canopy facing up on a padded table. Pin the damaged area flat to eliminate wrinkles and baste the patch to the outlined area. Turn the raw edges of the patch under 1/2 inch. Lock-stitch the patch using two rows of stitching around the edges of the patch with 8 to 10 stitches per inch; stitching around the edges of a patch must be continuous. Upon completion of a row of stitches, backstitch 2 1/2 inches on radial seams or hems and 1 1/4 inches on diagonal seams. If the patch is not anchored on a seam or hem, backstitch 1 1/4 inches. (See fig. 10-8.)

For all sewing of patches and other repair work on personnel parachute canopies, size E nylon thread must be used.

PR.257

Figure 10-7.—Filler patch applied with baseball stitch.

DOUBLE PATCHING

A hole, tear, or cut in the canopy greater than one inch square and less than 8 inches square must be patched with a double patch.

Use the same method for baseball stitching and applying filler patches as described for single patching. In order to measure and cut the outside patch, use the inside patch as a gage.

Place the inside patch on a piece of new material and cut the outside patch 1/4 inch larger on all sides except the side or sides that will be anchored to a seam or hem. Sides to be anchored to a seam or hem are cut to the same size as the inside patch.

The inside patch should be the smaller patch and must be applied first, so that its stitching will be covered by the outside patch.

Pin the outside patch to the canopy material, with the outside of the canopy facing up. Sew with size E nylon thread, 8 to 10 stitches per inch, using two rows of stitchings. For additional strength always try to anchor one or more sides of the patch to a seam or hem. NEVER sew through a suspension line. Figure 10-9 shows the method of double patching.

REPLACING PARACHUTE COMPONENTS

VENT RING

Broken or damaged vent rings cannot be repaired and must be replaced.

Open the seam holding the vent ring, remove the damaged vent ring and insert the new ring. Resew the hem using size E nylon thread, 8 to 10 stitches per inch. When the seam is completed backstitch 1 1/4 inch.

HARNESS/RISER ASSEMBLY

Inspect webbing for signs of contamination, cuts, fraying, burns, and loose or broken

11076

PR.258

Figure 10-8.—Single patching.

stitching. If any damage is found in excess of three stitches, strike the assembly from service and replace it in accordance with the applicable rigging and packing procedures.

If less than three stitches are loose or broken, repair the harness or riser assembly using nylon 6 cord. Lock-stitch over the original stitch and 3/4 inches on both sides, 4 to 6 stitches per inch.

HARDWARE

Inspect canopy quick-release fittings for breaks, corrosion, pitting, bends, dents, and

PR.260

Figure 10-10.—Attaching MBEU pilot chute connector cord.

CONTAINER REPAIR

Reconditioning of the container can be accomplished with or without a sewing machine. Patches, modifications, additions, attachment of cushions or liferaft cases, or other repairs of any nature may not be made while the parachute is in a packed condition. To do so is to risk the possibility of accidentally securing one of the main parts of the parachutes to the container and slowing or possibly preventing the proper opening of the parachute in an emergency.

To repair small holes, tears, or snags, 1/2 inch square or less, machine darn in the same direction as the weave, using size E nylon thread. To reinforce corners and edges, use flat webbing; do not use tubular webbing or light herringbone tape.

Cut flat webbing to size and sear ends; if necessary, remove container frame. Boxstitch webbing over the damaged area with size FF nylon thread, 8 to 10 stitches per inch.

To patch large holes, tears, or rips, the container repair material used must be the same as the type used to construct the container. Do not use overaged or salvaged material. Cut the patch large enough to fully cover the damaged area, overlap 3/4 to 1 inch and allow for the edges to be turned under 1/2 inch.

Place the patch over the damaged area, folding edges under 1/2 inch, sew two rows of stitches around the edge of the patch, and backstitch at least 3/4 inch.

Original manufacturing details of the container should be noted, and any repairs should reproduce these details as closely as possible.

GROMMET REPAIR

Defective or missing grommets must be replaced, using special dies. The same size grommet and grommet washer used in the manufacture of the container assembly must be used for the replacement.

To repair the damaged area, cover the hole in the container assembly with a square patch that is 3/8 inch larger than the grommet washer. Stitch the patch on all four sides with two rows of stitching. Turn raw edges under 1/4 inch and sew using 8 to 10 stitches per inch. The patching material must be nylon cloth, 7.5-ounce MIL-C-7219.

Care must be taken when applying the reinforcement so that the thickness around the grommet will not be increased to such an extent as to prevent the locking pins from passing through the holes in the cones. Care must be taken that the edges of the grommets are perfectly smooth and rounded so as not to obstruct the operation of the locking pins or retard the action of the grommets in slipping off the cones.

When cones have become corroded, have bent or broken flanges, or are worn where the grommets or end tabs bear, they must be replaced. In replacing cones on the container, sew with double 3-cord nylon thread. (Note the way other cones are sewn and follow the same sewing pattern.) Be sure the ripcord pin holes in the cones are in line with each other and also in line with the direction of ripcord pull.

In replacing loose or lost eyes, sew with double 3-cord nylon thread. (Note the way the other eyes are stitched and follow the same stitching pattern.) It should be noted that at each point of stitching, five turns of the doubled 3-cord is used. It does not matter in which order the stitches are made. Finish the stitching with the thread on the underside of the container material and tie off.

INSPECTION OF COMPLETED WORK

Though many of the more common repairs have been covered in this chapter, this should not be construed to mean that such procedures are the only authorized repairs. Any time a parachute assembly may be reasonably restored to operational condition, repairs may be made.

The primary concern in repairing any assembly is insuring that the basic integrity designed into the assembly is maintained. All

11079

repair work must be carefully inspected and compared to drawings and specifications at completion of work to insure absolute conformity to drawings.

QUALITY ASSURANCE

Examine the finished work and verify correctness of work. In no case may a man who accomplished the repairs perform his own quality assurance inspection.

SAFETY PROCEDURES

Due to employment of pyrotechnic devices on various parachute assemblies, the following precautions are cited to insure safety of personnel performing maintenance and repair operations.

NB-11 PARACHUTE ASSEMBLY

This assembly employs a fail-safe ballistic spreader gun. Do not remove folded canopy or suspension lines from container before installing spreader gun safety pin.

NB-7E AND LW-3B ASSEMBLIES

These assemblies employ a pyrotechnic static line cutter. Do not open the container by pulling on static line. Do not unpack the parachute before inserting the safety pin in the static line cutter device.

CARTRIDGE ACTUATED ASSEMBLIES

The NB-5, NB-7, NB-7D, NB-7E, NB-9, NB-10, and NB-11 assemblies employ cartridge operated automatic actuators (optional on NB-6, NB-8, and NS-3 parachutes for specific applications). Insure that the automatic actuator arming cable is not pulled accidentally while the automatic actuator is armed.

NATIONAL BUREAU OF STANDARDS-1963-A

CHAPTER 11

SEWING MACHINES

The nature of the PR's work in the maintenance and upkeep of aviator's equipment requires that he have a thorough knowledge of the minor adjustments to be made, and the proper lubrication of standard sewing machines. He must also be a skilled operator of these machines in order to keep flight clothing and survival equipment in good repair.

This chapter gives a background for obtaining this knowledge, but the actual skill in operating machines can be acquired only by practice at sewing on scraps of material or on jobs which may not require a lot of skill such as manufacture of pitot covers, small flags or pennants, etc. It behooves the PR striker to use as much of the time spent in the loft as is possible in practice sewing.

SEWING MACHINE FAMILIARIZATION

Sewing machines are divided into two types, OSCILLATING and ROTARY. Both types are operated by electric motors and are fitted with rheostats and special clutch arrangements which enable the operator to control the speed.

Oscillating type sewing machines are named for the action of the sewing hook, which rocks back and forth through half of one revolution to complete one stitch.

Rotary type sewing machines are also named for the action of the sewing hook, which makes two complete revolutions to complete one stitch,

The type of stitch commonly used and made by sewing machines in repair work is the lockstitch. The lockstitch makes use of two separate threads. One comes from the spool down through the eye of the needle, the other from the bobbin. In making the lockstitch, these two threads must become interlocked, as shown in figure 11-1.

The thread passing through the eye of the needle is pushed down through the material being sewn. As the needle travels downward to the material, a thread controller spring pulls on the needle thread to prevent any slack that might tangle the thread around the needle.

After the needle reaches its lowest position and starts its upward movement, a small loop of thread forms alongside the needle beneath the throat plate. The sewing hook catches this loop and carries it around the bobbin, which floats in its track in the bobbin case. By locking the loop of needle thread around the bobbin thread, the sewing hook forms the stitch.

As the needle completes its upward movement, the thread tension disks hold the needle thread firmly, and the thread takeup lever, rising quickly, pulls on the loop that has been formed and thus tightens the stitch. When the thread takeup lever reaches its highest position, the stitch is completed.

The standard sewing machine has four basic parts: bed, uprise, arm, and face. The BED houses the linkage from the safety clutch pulley to the sewing hook assembly; the UPRISE houses the arm shaft connection belt; the BALANCE WHEEL is connected to the arm shaft in the ARM which operates the needle bar mechanism in the FACE of the machine.

The machine is powered by an electric motor, which is connected to the motor driving pulley by a clutch. The motor is connected to the clutch by pressing the forward part of the foot treadle. The aft part of the treadle is the brake which acts upon the clutch.

The material to be sewn is held in position on the feed dog by the presser foot. The pressure of the presser foot upon the material enables the feed dog to push the material forward each time the needle goes up. The pressure of the presser foot on the material is released either by a knee lifter or a hand lifter. The presser foot can be raised by pushing the knee lifter to the right. The hand lifter is located behind the face of the machine. The

080111081

For maximum voltage production the pulse recurrence frequency should be equal to twice the resonant frequency of the charging circuit. To permit operation at more than one repetition rate, a charging diode must be connected in series with the charging choke. This diode would be connected at point D in figure 16-20. Figure 16-23 shows a multi-PRF modulator using a charging diode. The pulse-forming network is thus prevented from discharging after the maximum oscillation is reached. The diode also causes some additional damping in the circuit, so that the maximum value is slightly less than the original maximum value of almost twice the value of the d-c supply.

Because the diode maintains the voltage at practically twice the d-c supply for a considerable time the interval between times of closing the switching device can have any value greater than a half cycle of the charging oscillation.

The output voltage pulse from a d-c resonant charging network is about half the voltage to which the network is charged because the line impedance and load impedance are equal. Since the network is charged to nearly twice the supply voltage and the output pulse voltage is half the network charge, the usable voltage in the output pulse is about 0.9 of the supply voltage.

This type of pulse network is usually sealed in a metal box filled with oil which acts as an insulator. For that reason it is sometimes called a POTTED NETWORK. It is impossible to replace components in the line. Some lines using only a few elements are not potted. These do not generally give as nearly a rectangular output pulse, due to the smaller number of sections.

THE PULSE TRANSFORMER

In the circuits discussed thus far the load can be a magnetron and its associated circuits or the primary of a pulse transformer which has its secondary connected to the magnetron. The use of a high-voltage step-up transformer to furnish voltage for the magnetron makes possible the use of lower voltages in the pulse-forming network and thus simplifies the insulating problem. An advantage in using a transformer with two secondaries (bifilar windings), as shown in figure 16-21, is that it avoids having high voltage in the magnetron filament transformer. The bifilar windings have the same voltage induced into each since they are wound side by side. This winding

Figure 16-21.—A transformer with two secondaries makes possible the grounding of the filament transformer secondary.

makes it possible to connect a filament transformer, without high-voltage insulation, to the heater of the magnetron and to couple the high-voltage pulse between the cathode and plate.

A third need for the high-voltage pulse transformer is matching impedances, particularly where the radar antenna is remote from the set itself. Since the use of long transmission lines between the magnetron and the antenna makes the magnetron's operation somewhat erratic, it is desirable to have the magnetron near the antenna. This necessitates the use of long lines to carry the modulator pulse to the magnetron. In order to be able to use 50-ohm line for this purpose and still obtain an impedance match with the impedance of the magnetron (approximately 1,000 ohms), it is necessary to use a 4 1/2 to 1 step-up transformer at the magnetron end.

The pulse transformer must be specially designed because there are very high frequency components present in a rectangular pulse of such short duration. The core is usually silicon steel and has laminations in the order of 0.003 inch in thickness. In general a good pulse transformer must have low leakage inductance, low interwinding capacitance, and high primary inductance.

TYPES OF MODULATORS

There are two types of modulators—the line-pulsing modulator and the driver-hard-tube modulator. The line-pulsing modulator stores energy and forms pulses in the same circuit element. This element is usually the pulse

001105

PR. 261

Figure 11-1.—The lockstitch.

680 1082

presser foot may be lifted and locked into position by raising the hand lifter to its highest position.

OSCILLATING TYPE SEWING MACHINES

Two of the most commonly used oscillating type sewing machines are the 31-15 and the 7-33, both of which are discussed in this chapter.

SINGER SEWING MACHINE 31-15

The 31-15 is an oscillating type sewing machine which has a recommended speed of 2,200 stitches per minute and makes a lockstitch. The 31-15 is intended for sewing clothing. It is very good for nylon cloth sewing and can be used for sewing lightweight canvas up to 8 ounces. The number of stitches can be regulated from 7 to 32 stitches per inch.

When the 31-15 machine is in operation, the balance wheel turns over toward the operator. When hand-turning the balance wheel, always rotate in this direction.

The components of the Singer Sewing Machine 31-15 are shown in figure 11-2.

Lubrication

To insure easy operation and to prevent unnecessary wear of the moving parts, all sewing machines need oiling. When a machine is in constant use, it should be oiled twice a day. A new machine should be oiled more frequently when in constant use. A castor base oil is recommended since mineral base oil tends to gum the moving parts.

Oiling points for the 31-15 machine are shown in figures 11-3, 11-4, and 11-5.

Oil should be applied regularly to the shuttle bearing in the shuttle race. Occasionally remove the faceplate and apply oil to the bearings and joints that are uncovered.

Needles and Thread

The proper needle to be used on the 31-15 Singer Sewing Machine is class and variety 16 x87. Needles are available in various sizes and any of the following sizes may be used: 14, 16, 17, 18, 19, 21, 22, and 23. The size of thread and material used determines the size of needle to be used. Needles vary in size according to number: the smaller the number, the smaller the needle eye; the larger the number, the larger the needle eye. Needles do not vary in length within the same class and variety.

Orders for needles must specify the QUANTITY required, the SIZE number, and the CLASS and VARIETY number, separated by an "X."

An example of an order follows:

100 No. 18, 16 x 87 needles.

Best results will be obtained in using needles furnished by the manufacturer of the machine.

Figure 11-6 shows the six parts of a needle used in an oscillating type sewing machine.

The thread to be used on an oscillating type sewing machine is LEFT TWIST (also known as Z twist). Either right or left twist thread can be used in the bobbin, but to eliminate the possibility of mixing the machine and bobbin thread, it is advisable to order only left twist thread.

To determine the twist of thread, hold the thread as shown in figure 11-7. Turn the thread toward you with the right hand; if it is left twist, the strands will wind tighter; if it is right twist, the strands will unwind.

To determine the relative sizes of needles and threads that can be used, refer to table 11-1.

Operation

The following practices and procedures will help to insure safe and smooth operation of the sewing machine:

1. The balance wheel must always turn toward the operator.
2. Do not run the machine with the presser foot resting on the feed dog without material being under the presser foot.
3. Do not run the machine when both bobbin case and needle are threaded unless there is material under the presser foot.
4. Do not try to help the machine by pulling the material. You may bend or break the needle. If properly adjusted, the machine feeds the work without assistance.
5. The slide over the bobbin case should be kept closed when the machine is in operation.
6. Keep your head away from the takeup lever.
7. When running the machine do not take your eyes away from the needle and presser foot.
8. Keep your fingers from under the needle.

Setting the Needle

Turn the balance wheel toward you until the thread takeup lever moves upward to its highest

point; loosen the setscrew in the needle clamp; insert the needle ALL THE WAY into the needle bar so that the long groove of the needle is toward the left, and the eye of the needle is directly in line with the arm of the machine; then retighten the setscrew. NOTE: When setting any needle, always insert it with the long thread groove away from the bobbin.

Threading the Machine

Threading a sewing machine is a very simple job. The procedure may vary slightly with different models; but after working with the various machines in the loft, the task will become automatic.

G80f11084

PR.263

Figure 11-3.--Oiling points at the front of the machine.

The procedure for threading the 31-15 sewing machine is illustrated in figure 11-8 and described in the following paragraph.

Pass the thread from the thread stand to the thread post on top of the machine, right to left through the bottom hole, and then right to left through the top hole. Pass the thread from right to left through the top hole in the thread retainer (1). Pass the thread from left to right through the middle hole in the thread retainer (2). Pass the thread from right to left through the bottom hole in the thread retainer (3). The thread is then passed down and under from right to left between the tension disks (4). Draw the thread up into the thread takeup spring (5), drawing the thread up and beyond the spring end so that it comes out in the center of the spring. The thread is then placed under the tension thread guard (6). Pass the thread up and from right to left through the hole in the thread takeup lever (7). The thread is now drawn down through three thread guides (8), (9), and (10). Pass the thread from left to right through the eye of the needle (11). Draw about 2 inches of thread through the eye of the needle with which to commence sewing.

Removing the Bobbin Case

Before attempting to remove the bobbin case, turn the balance wheel toward you until the needle moves upward to its highest position.

Remove the slide in the bed of the machine for visibility, reach under the table with the left hand, and using the thumb and forefinger, open the bobbin case latch (1, fig. 11-9), and lift out the bobbin case (2).

11085

PR.264

Figure 11-4.—Oiling points at the back of the machine.

While the latch is held open, the bobbin is retained in the bobbin case. Release the latch, turn the open end of the bobbin case down, and the bobbin will drop out.

Winding the Bobbin

The bobbin winder is fastened to the table with its driving pulley in front of the sewing machine belt. The bobbin winder is so positioned to allow the pulley to drop away from the belt when sufficient thread has been wound on the bobbin.

Figure 11-10 illustrates the bobbin-winding operation. The procedure is as follows: Place the bobbin on the bobbin winder and push it on the shaft as far as it will go. Pass the thread from the spool down through the thread guide (1). Loop the thread around back and through the tension disks (2). The thread is then wound around the bobbin a few times and the pulley pushed up against the machine belt. The bobbin can be wound while the machine is being used for sewing. If there is no material under the presser foot, make certain that the presser foot is raised and not riding on the feed dog while winding the bobbin.

When sufficient thread has been wound on the bobbin, the pulley on the bobbin winder will drop back from the machine belt automatically. If the thread does not wind evenly on the bobbin, loosen the screw (3) in the tension bracket and move the bracket to the right or left as required; then tighten the screw. The amount of thread wound on the bobbin is regulated by the screw (4). To wind more thread on the bobbin, turn the screw to the right; to wind less thread on the bobbin, turn this screw to the left.

11086

PR.265

Figure 11-5.—Oiling points at the base of the machine.

PR.266

Figure 11-6.—Sewing machine needle adaptable to the 31-15 sewing machine.

PR.267

Figure 11-7.—How to determine the twist of thread.

Threading the Bobbin Case

Hold the fully wound bobbin between the thumb and forefinger of the right hand with the thread end running over the top toward the right, as shown in figure 11-11 (A). With the left hand hold the bobbin case as shown, with the thread slot near the top.

Place the bobbin into the bobbin case and pull the thread into the slot in the edge of the bobbin case (B). Draw the thread down under the tension spring and into the delivery eye at the end of the tension spring (C). When the free end of the thread is pulled, the bobbin will rotate clockwise if the bobbin case has been threaded properly.

Replacing the Bobbin Case

Hold the latch open on the threaded bobbin case with the thumb and forefinger of the left hand, with the latch in a horizontal position.

11087

Table 11-1.—Relative sizes of needles and thread.

Sizes of needles	Cotton thread size	Nylon thread size
18	24 x 4	A and B.
19	24 x 4	C.
21	24 x 4	E.
22	16 x 4	E.

Place the bobbin case on the center stud of the shuttle body. Release the latch and press the bobbin case back until the latch catches the groove near the end of the stud.

Preparing for Sewing

With the left hand, hold the end of the needle thread, leaving it slack from the hand to the needle. Turn the balance wheel toward you until the needle moves down and catches the bobbin thread. Continue to turn the balance wheel forward until the needle comes up and brings the bobbin thread up with the needle thread.

With the thread takeup lever at its highest position, lay both threads back under the presser foot.

Commencing to Sew

Place the edge of the material beneath the presser foot, lower the presser foot, turn the balance wheel by hand until the needle is in the material, and press lightly on the treadle. To prevent fouling the needle thread in the bobbin case, hold the ends of both threads until the first few stitches are made.

While sewing, hold the work flat, but do not pull or push on the material. Let the feed dog carry the work evenly under the presser foot and needle. If the operator pulls on the material, the needle bends, strikes the throat plate, and is either dulled, or more likely, broken. When the needle is about to cross a seam or other unusually thick or uneven place in the work, disengage the clutch, and hand-turn the machine over the rough place; otherwise, the needle may be broken or thrown out of time.

2. Bobbin case.

PR.269

Figure 11-9.—Removing the bobbin case.

Regulating the Tension

The tension on the needle thread should be regulated only when the presser foot is down. If the tension of the machine thread is not correct, it should be adjusted by turning the tension adjusting nut, as shown in figure 11-12. To INCREASE THE TENSION, turn the nut clockwise, to DECREASE THE TENSION, turn the nut counterclockwise.

The tension on the bobbin thread is regulated by the small screw in the bobbin case tension spring. To increase the tension turn the screw clockwise; to decrease the tension turn the screw counterclockwise.

This screw is very small and is easily lost if extreme care is not exercised in backing it out when decreasing the tension. If the screw is tightened excessively or is slightly too long, it will penetrate into the inside of the bobbin case and prevent removal of the bobbin.

When the tension on the bobbin thread has once been properly adjusted for a particular size of thread, it is seldom necessary to change it. A correct stitch can usually be obtained by varying the tension on the needle thread, which is an easier adjustment.

For ordinary stitching, the needle and bobbin threads should be locked in the center of the thickness of the material as shown in figure 11-13 (A). When adjusting the tensions, you will not have a cross section of the stitch.

If the tension on the needle thread is too tight, or if the bobbin tension is too loose, the thread will lie straight along the upper surface of the material and appear as small loops (fig. 11-13 (B)).

If the tension on the bobbin thread is too tight, or if that on the needle thread is too loose, the bobbin thread will lie straight along the underside of the material (fig. 11-13 (C)).

Regulating the Length of Stitch

The length of stitch can be checked at the time the tension of the stitch is checked, as a trial run of stitches is necessary during both procedures.

The length of stitch is regulated by the thumbscrew in the slot on the front of the upright of the machine. To LENGTHEN the stitch, loosen the thumbscrew and move the lever DOWN. To SHORTEN the stitch, loosen the thumbscrew and move the lever UP. When the desired length of stitch has been obtained by test running the machine on scrap material, tighten the thumbscrew.

Regulating the Pressure on the Material

Pressure on the material is regulated by the pressure regulating thumbscrew on top of the machine face. To increase the pressure, turn the thumbscrew clockwise. The pressure should be just heavy enough to enable the feed dog to move the work along evenly.

Removing the Work

Hand-turn the balance wheel toward you until the thread takeup lever is at its highest position. Raise the presser foot, either by the hand lever or by the knee lift, and draw the work and threads straight behind the presser foot. Cut the threads close to the material, leaving about 2 free inches of bobbin and machine thread.

Adjusting the Thread Takeup Spring

The thread takeup spring (fig. 11-12) should be set so that when the eye of the needle reaches the material on the downward stroke of the needle bar, the spring will be through acting on the thread, and will rest against the stop of the thread takeup spring regulator.

88011089

1. Thread guide.
2. Tension disk.
3. Setscrew.
4. Bobbin winder stop latch screw.

PR.270

Figure 11-10.—Winding the bobbin.

If the thread takeup spring is not correctly set, loosen the setscrew (2) in the arm of the machine and turn the tension adjusting stud to the right for more movement of the spring, or to the left for less movement. When the spring is correctly set, retighten the setscrew.

The tension on the thread takeup spring should be just sufficient to take up the slack of the needle thread until the eye of the needle reaches the material on its descent. To increase the tension on the thread takeup spring, loosen the tension adjusting stud and move the takeup spring from the recess in the regulator to the right between the regulator and the tension disks. When the required tension is obtained, securely tighten the tension adjusting stud and move the spring back into its position in the regulator recess. To decrease the tension, move the spring to the left between the regulator and the tension disks.

SINGER SEWING MACHINE 7-33

The class 7-33 sewing machine is a lockstitch heavy duty machine and is intended for use in sewing heavy canvas, webbings, and other material not adaptable to the lighter duty sewing machines. The only difference between the 7-31 and the 7-33 is that the 7-33 has the clutch on the motor, while the 7-31 has the clutch on the balance wheel. The operation and maintenance techniques are identical.

As on any Singer Sewing Machine, the balance wheel of the 7-33 should always turn toward the operator.

Lubrication

The 7-33 machine is oiled at all the oiling points shown in figures 11-14 and 11-15. The machine should be oiled twice daily when it is in

11090

PR.271

Figure 11-11.—Threading the bobbin case.

2. Setscrew

PR.272

Figure 11-12.—Adjusting the machine thread tension.

PR.273

Figure 11-13.—Properly and improperly adjusted tensions.

constant use. Use a castor base oil as recommended by the manufacturer.

Needles and Thread

The procedure for ordering needles is the same for the 7-33 machine as for the 31-15 sewing machine. Refer to table 11-2 for the relative sizes of needles and thread.

Operation

The procedure for operating the 7-33 sewing machine is the same as for the 31-15 sewing machine.

Setting the Needle

The same procedure may be followed with this machine as for the 31-15 sewing machine.

Threading the Machine

Turn the balance wheel toward you until the thread takeup lever (7, fig. 11-16) moves up to its highest position. Pass the thread from the thread stand to the thread post, right to left through the bottom hole then right to left through the top hole. Pass the thread through the two thread guides (1) and (2). Continue the passage of thread between the retainer disks (3), down and under the tension disks (4). Pass the thread into the loop of the thread takeup spring (5), under the wire loop (6), up, and from

11091
00011

forming network. The driver-hard-tube modulator forms the pulse in the driver; the pulse is then amplified and applied to the modulator. The hard-tube modulator has been replaced by the line-pulsed modulator. The reasons for this replacement are that the hard-tube modulator has lower efficiency, its circuits are more complex, higher power supply voltage is required, and it is more sensitive to voltage changes.

The line-pulsed modulator is easier to maintain because of its less complex circuitry and, for a given amount of power output, it is more compact and light. Since it is the principally used modulator in aviation radar, it is the only type that will be discussed at great length.

Before discussing the line-pulsing modulator, it is well to consider briefly the various types of charging circuits and to note their advantages and limitations. To do this, study figure 16-22 which shows the various types of charging circuits.

In the d-c resistance charging circuit (A), the pulse line or storage capacitance is represented as C_{st}. It is charged through R_{ch} to the value of the d-c voltage. During the pulse one-half the d-c voltage is applied to the magnetron (assuming the line impedance is matched to that of the magnetron) for a period of time determined by the line components. This is only 50 percent efficient. Therefore, it is necessary that the d-c voltage be twice the value needed for the magnetron. The time constant $R_{ch}C_{st}$ must be large in comparison to the period of the repetition frequency. This insures that the line will fully charge between pulses but will not discharge appreciably through the source and R_{ch} during the pulse.

In the d-c resonance charging circuit (B), resistor R_{ch} is replaced by an inductance L_{ch}. As C_{st} charges, the current through L_{ch} builds up a magnetic field. This field causes current to continue after C_{st} is charged to E_{bb}. The charge will reach a peak of approximately 1.9 times E_{bb} after which it starts decreasing. If the modulator is triggered at the instant of maximum charge, the voltage applied to the magnetron is about 95 percent of E_{bb}. This necessitates that the resonant frequency of L_{ch} and C_{st} be one-half the PRF of the radar. The firing time is very critical if advantage of the maximum voltage is to be obtained.

The difficulty encountered in the preceding circuit is overcome by adding a diode in series with the charging element. Circuit (C) prevents the line from discharging after reaching its peak. This means that the time of firing can occur any time after the peak is reached. Therefore, the frequency at which L_{ch} and C_{st} resonate is equal to or greater than one-half the PRF. The disadvantage of making the firing time less critical is that the voltage to which the pulse forming line charges is decreased by the drop across the diode to about 1.8 times E_{bb}. This makes the efficiency of this circuit about 90 percent.

Circuit (D) has the pulse line charging from an a-c source. In this circuit, the charging line is prevented from discharging by a diode in series with it. Further, in this circuit it is necessary that every trigger pulse come at a time when the diode plate is negative; otherwise the diode and the switch will short circuit the a-c source. Therefore,

$$T_r = NT_{ac}$$

where

T_r = time between trigger pulses

N = 1 or some other whole number

T_{ac} = time of a cycle of the a-c source voltage

The voltage to which the line charges is almost the peak value of the a-c wave so that the efficiency is about 70 percent.

In circuit (E), the diode is replaced by the inductance L_{ch}. This inductance, along with C_{st}, forms a resonant circuit which is resonant at the frequency of the a-c supply voltage. In this circuit the switch may be closed at any peak of oscillations. Usually it is closed at the first peak. At this time the voltage is approximately π times the peak value of the a-c voltage. In addition $T_r = T_{ac} = 2\pi \times \sqrt{L_{ch}C_{st}}$. If the switch is closed at the second peak, the voltage will be nearly twice as high. This type of charging gives voltages higher than the source voltage.

The Line-Pulsing Modulator

This discussion will serve a dual purpose—it will explain the theory of operation of a typical line-pulsing modulator and will also summarize the function of the various modulator components already explained in this chapter.

1106

PR.274

Figure 11-14.—Oiling points at the front of the 7-33 sewing machine.

back to front through the hole in the thread take-up lever (7). Now pass the thread down through the thread guide (8), into the slot in the vibrating presser bar (9), and on down through the thread guide (10) which is located on the needle clamp. The needle is now threaded from left to right through the eye of the needle (11). After the needle is threaded as shown in figure 11-16, pass the thread down through the hole in the lifting presser foot (12). Draw about 4 inches of thread through the hole in the lifting presser foot with which to commence sewing.

Notice that the lubricating cup has been by-passed. No lubricant is used on the threads and cords used in the manufacture or repair of parachutes.

Removing the Bobbin

Turn the balance wheel forward to bring the needle bar and thread takeup lever to its lowest position. With the aid of the shuttle opening tool or a small screwdriver, insert the blade end in the slot in the spring latch beneath the shuttle cylinder (fig. 11-17). Press the latch away from the cylinder and it will swing out. The bobbin will then slide out of the shuttle cylinder.

Winding the Bobbin

Place the bobbin on the bobbin winder spindle and push it up closely against the shoulder. The small pin in the shoulder must enter the slot in the bobbin.

Pass the thread from the thread stand through the hole in the left side of the bobbin from the inside. Push the bobbin winder pulley up against the balance wheel and place the bobbin winder latch in position. Raise the presser foot and start the machine. The end of the thread should be held until a few turns are wound on the bobbin to prevent slipping. When sufficient thread has been wound on the bobbin, the bobbin winder will stop automatically.

11092

PR.275

Figure 11-15.—Oiling points at the back of the 7-33 sewing machine.

Replacing the Bobbin and Threading the Shuttle

Take the bobbin between the thumb and forefinger of the left hand as shown in figure 11-18. The free end of the thread should be drawn off from the underside toward the right. Place the bobbin in the shuttle cylinder as far as it will go. Draw the thread into the slot in the cylinder (1) and under the tension spring into the delivery eye (2). Push the shuttle cylinder in until it is locked by the spring latch. There should be about 3 inches of thread hanging free from the shuttle with which to commence sewing.

Regulating the Tension

The tension on the needle thread is regulated by the thumb nut at the front of the thread retainer disks. The tension on the thread retainer disks should be just enough to cause the tension wheel to turn when the thread is taken from the spool.

The tension on the bobbin thread is regulated by the small screw which holds the tension spring to the shuttle cylinder. To increase the tension, turn the screw clockwise. To decrease the tension, turn the screw counterclockwise.

The tension on the machine and bobbin threads should be checked by test running a row of stitches on scrap material. The lockstitch should lock in the center of the material as described for the 31-15. When sewing webbings with the 7-33 sewing machine, the specifications for webbing sewing should be checked to determine at what ply of the webbing the stitch should lock.

Regulating the Length of Stitch

The procedure for regulating the stitch on the 7-33 sewing machine is the same as for the 31-15.

Regulating the Pressure on the Material

The pressure on the material is regulated by means of the hexagon head screw (1, fig.

11093
sebri

Table 11-2.—Relative sizes of needles and thread.

Machine	Needle class and variety	Needle sizes	Classes of work	Needle size	Cord size
7-31 or 7-33	7 x 1	19, 21, 22, 23, 24 25, 26, and 27.	Medium to heavy canvas.	24	3-cord
7-31 or 7-33	7 x 5	28, 29, 30, and 31.	Heavy canvas and webbing.	28	6-cord

11-19). Loosen the hexagon head locknut (2) and turn the adjusting screw clockwise to increase the pressure or counterclockwise to decrease the pressure on the spring (3). When the desired pressure has been obtained, hold the adjusting screw with a wrench to keep it from turning while the locknut is being tightened against the bracket (4).

The pressure should be just heavy enough to enable the feed dog to move the work along evenly, and to prevent the work from rising with the needle.

Preparing for Sewing

The same sewing preparatory procedures are used for the 7-33 as for the 31-15 sewing machine except there is no knee lifting device. The hand presser bar lifter is the only device provided for lifting the presser foot on the class 7-33 sewing machine.

Removing the Work

Stop the machine and raise the thread takeup lever to its highest position. Draw about 3 inches of thread through the thread retaining disks. Raise the presser foot and draw the work back, cutting the threads close to the material. Leave the ends of the threads under the presser foot.

Modification of Presser Foot for Webbing Sewing

The modification of a presser foot is illustrated in figure 11-20. The presser foot should be cut along the dotted line, removing the right portion of the foot. After cutting, the edges should be filed down to a smooth round finish.

Parachute harness and webbing sewing is classified as a major repair. However, there are various other sewing projects requiring webbing sewing, such as slings, bridles for tow targets, and nylon barrier repairs.

ROTARY TYPE SEWING MACHINES

SINGER SEWING MACHINES CLASS 111

111 W 150 Sewing Machine

The 111 W 150 sewing machine is a high-speed, single-needle, lockstitch, compound feed machine employing a gear driven rotary hook with a vertical axis. It is designed for sewing mediumweight fabrics such as flight clothing, nylon, twills, and lightweight canvas.

111 W 151 Sewing Machine

The 111 W 151 sewing machine is also a single-needle, lockstitch, rotary hook machine, intended for high-speed straight stitching of mediumheavy materials.

The 111 W 151 sewing machine differs from other models of the class 111 machines in that it has a single presser foot instead of the alternating presser foot.

12. Hole in the lifting presser foot.

PR.276

Figure 11-16. —Threading the 7-33 sewing machine.

111 W 152 Sewing Machine

The 111 W 152 sewing machine is a single-needle, lockstitch, compound feed machine with a vertical axis sewing hook. This machine has alternating pressers with a 3/8-inch lift. It has a safety clutch which prevents the hook from being damaged or getting out of time due to accidental strain.

111 W 153 Sewing Machine

The 111 W 153 sewing machine is similar to the 111 W 152, but it is used for sewing heavy work such as automobile and truck upholstery, tents, awnings, and leather flight jackets.

111 W 154 Sewing Machine

The 111 W 154 sewing machine is also similar to the 111 W 152, but its alternating pressers have a lift of 1/2 inch and the machine is designed for stitching upholstery work and leather coats and binding heavy materials such as felt padding.

111 W 155 Sewing Machine

The 111 W 155 sewing machine is similar to the 111 W 154 except that its maximum stitch length is 3 1/2 to the inch, and it has an adjustable lifting eccentric for instantly setting the alternating pressers to the minimum amount of lift required for the work to be sewn.

Lubrication of the Class 111 Sewing Machines

Figures 11-21 through 11-24 show the various lubrication points on class 111 sewing machines. Oiling points are indicated by the unnumbered

C11095

2. Delivery eye and tension spring.

PR.278

Figure 11-18.—Replacing the bobbin and threading the shuttle.

arrows. Familiarization with the nomenclature of the machines may also be accomplished by studying these illustrations.

To lubricate the class 111 machine, swing back the top cover and oil the bearings, then replace the cover.

Loosen the thumbscrew in the upper end of the faceplate, turn the faceplate upward, and oil the wick and bearings as shown in figure 11-22. After oiling, turn down the faceplate and tighten the thumbscrew.

Turn the machine back on its hinges and apply oil at the places designated by the arrows in figure 11-24. All contacting parts on the bottomside of the machine should also be oiled.

To lubricate the hook, remove the bed slide and place oil in the oil well (fig. 11-23). This will lubricate the upper hook bearing and the mechanical opener mechanism.

The small green felt pad on the side of the bobbin case should be kept wet with oil to lubricate the hook race. When this pad is wet, it appears nearly black; when it appears light green, it indicates that it is dry. When a machine is new, oil should be applied to this felt pad EACH TIME A BOBBIN IS REPLACED.

11096

PR.280

Figure 11-20.—Modification of presser foot for webbing sewing.

Needles and Thread

The thread used on rotary type sewing machines is left twist. To determine the twist of thread, refer to figure 11-6.

Table 11-3 lists the class and variety of needle and the needle size range for each of the class 111 machines.

The size of needle to be used is determined by the size of the thread and material used. The thread must pass freely through the eye of the needle. If rough or uneven thread is used, or if it passes with difficulty through the eye of the needle, the machine will not function properly.

Needles used on rotary type sewing machines are ordered the same way as those for oscillating type sewing machines.

The needles for the rotary type sewing machines have 7 parts. This is one more part than the needles for the oscillating machines. The additional part is the SCARF, which is a small indention just above the short thread groove. The purpose of the scarf is to permit the point of the sewing hook to come close enough to pick up the needle thread without striking the needle.

Operation

Operation of the rotary type sewing machines is the same as for the oscillating sewing machines.

Setting the Needle

Turn the balance wheel toward you until the needle bar moves up to its highest position. Loosen the setscrew in the needle bar and slip the needle up into the bar as far as it will go. The needle must be inserted with its long thread groove toward the left; the eye of the needle being directly in line with the machine bed. Retighten the setscrew.

Threading the Machine

Pass the thread from the thread stand from back to front through the lower hole (1, fig. 11-25) in the thread post on top of the machine, then from right to left through the upper hole (2) in the post. Pass the thread down through hole (3), up through hole (4), and down through hole (5) in the thread guide on the front of the machine. Continue the thread over from right to left between the tension disks (6), and down, from right to left around the thread controller (7). Then the thread should go up into the fork (8) in the thread controller disk against the pressure of the wire controller. The thread is then passed up through the thread guide (9), and from right to left through the hole in the thread take-up lever (10). Pass the thread down through the thread guide (11), and between the felt pad and the felt pad retainer finger (12). (If the machine you are threading does not have the felt pad and retainer finger installed, bypass this component.) Finish the threading by passing the thread down through the thread guide (13), through the thread guide (14) at the bottom of the needle bar, and from left to right through the eye of the needle (15). Always thread a needle toward the bobbin.

Removing the Bobbin

To remove the bobbin draw out the right-hand slide plate in the bed of the machine. Insert the fingernail of the forefinger under the latch, raise the latch, and lift the bobbin out. (See fig. 11-26.)

11097

10. Throat plate
11. Presser foot.
12. Needle bar.

PR.281

Figure 11-21.—Front of machine, showing oiling points.

Winding the Bobbin

To wind the bobbin and adjust the bobbin winder, follow the procedure given for the 31-15 sewing machine.

Replacing the Bobbin and Threading the Bobbin Case

Hold the bobbin between the thumb and forefinger of the right with the thread drawing out on the bottom from left to right. Place the bobbin on the center stud of the bobbin case, then push down the latch.

Draw the thread into the slot (1), and under the back of the projection (2). Leave a loose end of thread about 2 inches long above the slide. When closing the slide plate, leave just enough space for the thread to pass through when it is first picked up by the needle.

Regulating the Tension

The tension on the needle thread is regulated by the tension thumb nut located at the front of the tension disks on the front of the machine. To increase the tension, turn this thumb nut

11698

1. Hand lift for presser foot.
2. Vibrating presser bar thumbscrew.
3. Needle bar.
4. Vibrating presser bar.
5. Presser bar.
6. Presser foot.

PR.282

Figure 11-22.—End of machine, showing oiling points.

clockwise. To decrease the tension, turn the thumb nut counterclockwise.

The tension on the bottom (bobbin) thread is regulated by means of the small screw nearest the center of the tension spring on the outside of the bobbin case, as shown in figure 11-26. To increase the tension, turn this screw clockwise. To decrease the tension, turn the screw counterclockwise.

Regulating the Length of Stitch

The number of stitches per inch is stamped on the stitch indicating disk which can be seen through the hole on the uprise.

To change the length of stitch, press down the feed regulating stud (plunger), located in the bed of the machine. At the same time turn the balance wheel slowly until the plunger enters a notch in the adjustable feed eccentric disk. Continue to hold the plunger and turn the balance wheel forward or backward until the number of stitches per inch desired can be seen through the hole in the front of the uprise. Disengage the plunger by releasing it.

Regulating the Pressure on the Material

The pressure on the material is regulated by the presser bar regulating screw at the back of the sewing machine. The screw acts on a flat spring. To increase the pressure, turn this screw downward. To decrease the pressure, turn this screw upward. The pressure should be only heavy enough to enable the feed to move evenly along whatever thickness of material you are using.

Preparing for Sewing

With the left hand, hold the end of the needle (machine) thread, leaving it slack from the hand to the needle. Turn the balance wheel over toward you until the needle moves down and up again to its highest position. If the sewing machine is properly timed, this will bring the bobbin thread up with the machine thread through the hole in the feed dog. Lay the threads back under the presser foot and close the slide.

Place the material under the presser foot. Lower the presser foot either by hand or by the knee lift, and commence to sew. Start the sewing by turning the balance wheel over toward you as you depress the treadle.

Removing the Work

After the machine has stopped, move the thread takeup lever to its highest position. Raise the presser foot, draw the work back, and cut the threads close to the material. Lay the ends of the threads back under the presser foot.

SINGER SEWING MACHINE 112 W 140

The 112 W 140 sewing machine has two needles, two gear-driven rotary sewing hooks, and makes the lockstitch. It has a compound feeding mechanism, consisting of needle and

11099

1. Balance wheel.
2. Top cover.
3. Presser bar spring regulating screw.
5. Thread post.
6. Knee lift linkage.
7. Bed slide.

PR.283

Figure 11-23.—Rear of machine showing oiling points.

drop feed. This machine is designed for stitching flight suits, coats, and other light and medium weight fabrics requiring a compound feed.

For bulky work such as tents, awnings, etc., which require two simultaneous parallel rows of lockstitching, the 112 W 116, equipped with a puller feed, is recommended.

Needles for machine 112 W 140 are of class and variety 135 x 7 and are made in sizes from 12 to 24.

When the machine is new, it should not be driven at a speed exceeding 3,000 stitches per minute. After the first few days, the machine may be driven at its recommended maximum speed of 3,500 stitches per minute. This speed depends on the nature of the work and the ability of the operator.

Lubrication

All the parts of the 112 W 140 sewing machine can be oiled without turning the machine back on its hinges. Oil should be applied to each of the places designated by arrows in figures 11-27, 11-28, and 11-29.

The type of oil to be used and the intervals of oiling are the same as given for the 111 series sewing machines.

The hook is lubricated as shown in figure 11-30. Oil should be placed in the oil well as indicated. The oil will flow to both the upper and lower bearings and also lubricate the mechanical opener mechanism.

The small green felt pads on the side of each bobbin case should be kept wet with oil to lubricate the hook races. When these pads are wet they appear nearly black; when they appear light green, it indicates they are dry. When a machine

1011100

PR.284

Figure 11-24.—Base of machine, showing oiling points.

Table 11-3. —Data for class 111 sewing machines.

Sewing Machine	Stitches per minute	Stitches per inch	Needle class and variety	Needle size range
111 W 150	3,500	5 to 32	135 x 7	7 to 24
111 W 151	3,500	5 to 32	135 x 17	14 to 26
111 W 152	2,900	5 to 32	135 x 17	12 to 24
111 W 153	2,900	5 to 32	135 x 17	12 to 24
111 W 154	2,900	5 to 32	126 x 11	22 to 27
111 W 155	3,500	3 1/2 to 32	135 x 17	12 to 24

is new, oil should be applied to these felt pads each time a bobbin is replaced.

Setting the Needles

Turn the balance wheel over toward you until the needle bars and the thread takeup lever moves to its highest position. Loosen the set-screw in the needle holders and slip the needles up into the holder as far as they will go. Make sure the inside needle (one nearest the upright part of the arm) has its long thread groove toward the left. The outside needle (one farthest from the upright part of the arm) must have its long thread groove toward the right. The eyes of both needles must be directly in line

Figure 16-22.—Types of charging circuits.

The modulator (fig. 16-23) is of the line-pulsing type. The pulse-forming network undergoes a charge-discharge cycle at a rate (PRF) which is established by the master-trigger generator and which is consistent with the pulse width in use and the maximum power capabilities

with the machine bed. After alining the needles, tighten the setscrews.

Replacing the Bobbins and Threading the Bobbin Cases

The removal and winding of the bobbins is accomplished the same as for the 111 sewing machines. Both bobbins should be wound and replaced at the same time.

1. Slot in the bobbin case.
2. Projection on the bobbin case.
3. Bobbin case latch.
4. End of bobbin thread.
5. Bobbin.
6. Tension adjusting setscrew.

PR.286

Figure 11-26.—Bobbin case threaded.

The following instructions apply to both of the bobbin cases.

Hold the bobbin between the thumb and forefinger of the right hand, the thread drawing on the bottom from left to right. Place the bobbin on the center stud of the bobbin case then push down the latch, as shown in figure 11-31.

Draw each thread into the slot (1) located in the edge of the bobbin case, and back of the projection (2). Leave a loose end of each thread about two inches long above the slide. When closing the slides, leave just enough space for the threads to pass through when being picked up by the machine threads.

Threading the Machine

The 112 W 140 sewing machine is threaded in practically the same way as the 111 series machines. The only exception is that there are two upper thread guides and two tension disks, as shown in figure 11-32. With the exception of the upper thread guides and tension disks, the two threads run parallel. Each needle is threaded from inboard to outboard (always toward the bobbin).

11102

PR.287

Figure 11-27.—Oiling points at the front of the machine.

After the machine has been threaded, the preparation for sewing and removal of the work are the same as for the 111 series machines.

Adjusting the tensions, regulating the length of stitch and regulating the pressure on the material are also accomplished the same as for the 111 sewing machine.

SINGER SEWING MACHINE
143 W 2 AND 3

The zigzag sewing machine is an excellent sewing machine for the manufacture of parachutes. This type of machine is not as common as those previously described, but it has unlimited uses in the repair and maintenance of parachutes and survival equipment and will be found in many parachute lofts.

The 143 W 2 is a high-speed sewing machine which has an aluminum alloy vibrating needle bar frame and a rotary hook. It is intended for overseaming and zigzag stitching on fine and general fabrics and lightweight leather. It has ball bearings on the rear end of the arm shaft and hook driving shaft. The needle bar has a maximum throw of 3/16 inch, vibrating both sides of a centerline.

The 143 W 3 sewing machine is similar to the 143 W 2 except that the needle has a maximum throw of 5/16 inch.

The maximum speed recommended for machine 143 W 2 is 3,500 stitches per minute, and for machine 143 W 3, 3,000 stitches per minute, the speeds depending on the material being sewn.

Lubrication

Lubrication points for these machines are indicated by arrows in figures 11-33 through 11-36. When in continuous use, they should be oiled twice a day.

Needles and Thread

The needles for the 143 W 2 and 3 sewing machines are of class and variety 135 x 7; the sizes from 7 to 24.

Left twist thread should be used on these machines. To make a smooth even stitch with

PR.288

Figure 11-28.—Oiling points at the back of the machine.

the sewing machine, use good, firmly twisted and smoothly finished thread. The thread should pass freely through the eye of the needle.

Setting the Needle

Push the needle up in the needle bar as far as it will go, with the LONG THREAD GROOVE TO THE FRONT, and secure it firmly with the setscrew. It may be necessary to turn the needle slightly to the right or left for some threads if stitches are missed.

Bobbin and Bobbin Case

The procedure for removing the bobbin case, winding the bobbin, threading the bobbin case, and replacing the bobbin case is the same as for the 31-15 sewing machine. The only exception to this is that when threading the bobbin case, the thread should draw from the BOTTOM from left to right, instead of from the top as given for the 31-15.

Threading the Needle

These machines are threaded in the same way as the 111 series machines, described earlier in the chapter. When threaded up to the needle, thread the needle from the front through the eye to the back. The long thread groove should be in front when the needle is properly set in the needle bar.

Regulating the Length of Stitch

Press the stitch regulator lever and at the same time turn the balance wheel over toward you until the lever engages the notch in the stitch regulator flange. Continue to hold the lever in the notch in the flange and at the same time turn the balance wheel backward or forward, as required. When the desired number of stitches is obtained, as indicated on the stitch regulator flange (seen through small holes on the upright above the lever), release the lever.

11104

PR.289

Figure 11-29.—Oiling points at the end of the machine.

PR.290

Figure 11-30.—Hook lubrication.

Regulating the Width of Throw

The width of throw of the zigzag stitch is regulated by means of the needle vibrator regulating spindle head on the front of the machine. To increase the width of the zigzag stitch, turn the regulating spindle head counterclockwise. To decrease the width of the zigzag stitch, turn the regulating spindle head clockwise.

The thread tensions are regulated as given for the 111 class machines, and the pressure on the material is regulated by the thumbscrew, located on top of the sewing machine face.

Turning Corners

Stop the machine while the needle is rising, but before it is out of the material, raise the presser foot and turn the work. This method uses the needle as a pivot.

Removing the Work

Raise the presser lifter (either hand or knee), turn the machine by the balance wheel until the takeup lever is at its highest position and draw the work away from you. If the threads do not draw out easily, the takeup lever is not in the right position. If the machine is stopped as directed, the needle will not be unthreaded when starting to sew, even if only a short end is left through the eye of the needle.

1. Slot in the edge of the bobbin case.
2. Projection on the side of the bobbin case.

PR.291

Figure 11-31.—Threading the bobbin case.

SERVICING AND ADJUSTMENT

Service manuals covering each class and variety of sewing machines are furnished with new machines. Replacement manuals may be ordered, through open purchase, from the sewing machine manufacturer. Servicing of all sewing machines is to be performed in accordance with the applicable sewing machine maintenance manual. Adjustments to sewing machines must be made only by qualified personnel.

CHAPTER 12

FASTENERS

Textile products may be joined by many different methods, depending upon each individual requirement. These methods include sewing (by hand, or by machine), cementing, and the use of various fasteners and fastening devices.

Fasteners have been designed for almost every possible manner in which textile products may be united. Some fasteners act as anchoring and reinforcing points for pockets and corners, while others are snaps, and release their grip when pulled in the proper manner.

The PR must be throughly familiar with—and able to repair or renew—each type fastener. These fasteners include:

1. Snap fasteners.
2. Speedy rivets.
3. Grommets.
4. Slide fasteners (zippers).
5. Velcro tape fastener.

SNAP FASTENERS

The snap fasteners most commonly used in the manufacture of parachutes and for general utility work in the parachute loft are described in the following paragraphs.

WIRE SPRING CLAMP TYPE FASTENERS

The wire spring clamp type fastener is furnished in two sizes, regular (MS 27980) and small (MS 27981). In the parachute loft the wire spring clamp fastener is popularly called DURABLE DOT or DURA DOT. Figure 12-1 shows the parts of the regular wire spring clamp type fastener. In comparison to the regular size, the button of the small wire spring clamp type fastener has a dimension of 17/32 inch, with smaller corresponding parts.

Both the regular and the small wire spring clamp type fasteners are designed with a strong grip, and they will release or separate when pulled in any direction. The regular size wire spring clamp is the one most frequently used. It is used in the manufacture of back pads and parachute packs. It is also used on flight clothing where the additional security offered by the THREE-WAY SNAP is not needed. NAF blueprints refer to the parts of this fastener as button, socket, stud, and eyelet.

All parts are plated. Notice the difference in the studs in figure 12-1. These studs make it possible to mount the fastener in fabric, wood, or metal.

THREE-WAY LOCKING SNAP TYPE FASTENERS (MS 27983)

The three-way snap is manufactured in one size only, and is used on flight clothing, parachute packs, and back pads. (See fig. 12-2.) This fastener will open only when lifted from the side with the dot. It is therefore not used where any quick opening devices or quick releasing action is required. For example, the lift web keepers of a seat type parachute are equipped with the regular wire spring clamp fastener, while the two vertical keepers, which hold the shoulder straps and the back strap, are fitted with three-way locking snaps.

CURTAIN TYPE FASTENERS (MS 27977)

The curtain type fastener (lift-the-dot) is manufactured in two sizes, large and small. The parts of the large lift-the-dot, with various types of studs, are shown in figure 12-3. These fasteners have many uses, especially for truck and boat covers. The small lift-the-dot is the same as the large one, and designed on a smaller scale for use on lighter work where the bulkiness and weight of the large lift-the-dot are not desired.

11111

Figure 16-23.—A typical line-pulsing modulator and magnetron circuit.

of the transmitter. The modulator consists of artificial-line pulse-forming network Z401; hydrogen-thyratron switch tube V405; holdoff or charging diode V403; inverse-diode V404; resonant charging choke L401; and magnetron pulse transformer T404, the double-wound secondary of which supplies a pulse of power to the magnetron cathode circuit each time the line is discharged. The switching device which controls the discharge of the line is a hydrogen-thyratron tube controlled by the trigger from the radar's synchronizer.

When system power is applied, current to charge the pulse-forming network is drawn from the power supply through resonant charging choke L401 and charging diode V403. The flow of this current establishes a magnetic field in the resonant charging choke. Charging is rapid up to the point at which the pulse-forming network charge nearly equals the peak power supply voltage, approximately plus 2,500 volts d. c. The rate of charge drops sharply, and the magnetic field built up in the resonant charging choke collapses. By this self-inductance, a voltage approximately twice the power supply peak voltage is rapidly established. The tendency of the resonant charging choke to oscillate is halted abruptly at its first positive peak by the rectifying action of the charging diode and the pulse-forming network is held at this high potential. Discharge of the capacitors within the pulse-forming network is prevented by charging diode V403. Inverse-diode V404, and thyratron switch V405 are inoperative and hence appear as infinite impedances and do not provide a discharge path for the network.

The master-trigger generator in the synchronizer supplies a trigger voltage to the grid

1108011

PR.297

Figure 12-1.—Regular wire spring clamp fastener.

GLOVE SNAP TYPE FASTENER (MS 27984)

Figure 12-4 illustrates this type fastener, which is generally used on lightweight flight clothing.

INSTALLATION OF SNAP FASTENERS

Figures 12-5 through 12-7 illustrate the methods and tools employed in the installation of the regular wire spring clamp type fastener, large curtain type fastener, and the glove snap type fastener.

Setting Tools

In order to properly install the various types of fasteners used in the loft, it is essential to use the proper tool (chucks and dies) for the fastener being installed.

A fastener kit which consists of a small cabinet, five drawers, and a supply of assorted fasteners and setting tools is useful in the setting of snap fasteners.

The fasteners, along with their corresponding chucks and dies, are replenishable through regular supply channels.

11112

PR.298

Figure 12-2.—Three-way locking snap type fastener.

GROMMETS

The grommet is an eyelet, made of metal, rubber, or fabric. It is used as a reinforcement around a hole or cut, usually on the edge of an item where lacing or similar fastening is required. Examples of these are lacings on tent flaps and locations for securing the side flaps on parachutes.

The types of grommets most commonly found in a parachute loft are the plain grommet and the spur grommet. (See fig. 12-8 (A).) The plain grommet is used in lightweight materials, where there will be very little stress. The spur grommet is designed with teeth in the outer ring of the washer to aid in holding in heavy or loosely woven fabric and in places where considerable stress will be placed on the grommet. Design specifications for grommets are found in Air Force-Navy Aeronautical Standard Drawing AN 230.

The grommet used on parachute side flaps is a plain type, specially manufactured of chrome-plated metal. It is set in the parachute side flaps under a process which fuses the edge of the hole in the material and prevents the circular cut from fraying. This type of grommet is shown in figure 12-8(B).

Grommets may be set either by hand or by the hand press. The hand press makes a neater job and should be used whenever possible. Figure 12-9 illustrates the hand press dies and chucks used to set a plain or spur grommet. When setting grommets, the material should be reinforced with a hem or patch before the grommet is set.

SPEEDY RIVETS

Speedy rivets may supplement stitching as an additional reinforcement. One very popular use is in the open corners or pockets of certain types of clothing. They are also used to join two pieces of fabric or to secure a loop in a leather belt.

REMOVING FAULTY FASTENERS

Fasteners may be removed by different methods. The method used depends on the type fastener being removed, the material from which the fastener is being removed, and the person doing the job.

SNAP FASTENER REMOVAL

A damaged snap fastener is removed by cutting the shank or post securing the socket of one half and the stud of the other half. A sharp pair of end cutting pliers will do the job easily; however, considerable care must be taken to prevent cutting the fabric between the crimped shanks or extensions.

Some PR's prefer to drill the fastener out, and in some cases where the material is brittle or otherwise easily damaged, this is the better method. However, the fastener must be secured in some manner to prevent it from turning and tearing the fabric during the drilling.

GROMMET REMOVAL

Grommets are removed by prying the shank away from the washer until the shank is uncrimped enough to permit the washer to be withdrawn. They may also be removed by cutting the shank with a chisel. This raises the washer enough to permit gripping it with a pair of pliers for removal of the washer.

SPEEDY RIVET REMOVAL

Use a pair of diagonal cutting pliers to remove a speedy rivet. Cut the crimped shank halfway between the two parts, taking care not to damage the fabric.

SLIDE FASTENERS

The types of slide fasteners (zippers) used on flight clothing and other items of aviation

11113

PR.299

Figure 12-3.—Large curtain type fastener (lift-the-dot).

equipment are shown in figure 12-10. Figure 12-11 shows the parts of a slide fastener.

SLIDE FASTENER CONSTRUCTION

A slide fastener consists of two rows of teeth (hollow cones or scoops) facing each other. When brought together at the proper angle, each tooth is designed to fit within the tooth opposite.

When closed, the slide fastener teeth cannot be parted except through use of the slider which, when moved, displaces the teeth at the proper angle for meshing and unmeshing.

11114

PR.300

Figure 12-4.—Glove snap type fastener.

PR.301

Figure 12-5.—Installing the regular wire spring clamp type fastener.

The small clips (stops) at the top and bottom of the slide fastener are designed to prevent the slider from running off the track. Separating type slide fasteners do not have a bottom stop, but are equipped with a pin and retainer arrangement to facilitate separating of the slide fastener.

SLIDE FASTENER OPERATION

Ordinary slide fasteners are designed for flat, smooth operation, and both hands are required for proper functioning. The chain should be stretched taut with one hand and the slider worked (without force) with the other.

When operating a slide fastener installed in a garment made of soft nappy material, or lined with wool or fur, do so with care to prevent the nap or wool from jamming the slider.

Very often grease or oil deposits lodge between the tiny hollow parts of the teeth and accumulate dirt and lint. This causes stiff operation of the slider. A dirty or gummed chain should be cleaned with an old toothbrush or a pipe cleaner saturated with Stoddard solvent or other similarly approved cleaning solvent. After each cleaning, the chain should be lubricated by applying one drop of oil or a small amount of graphite between the thumb and forefinger and running the chain up and down between the fingers several times.

A brief inspection will determine whether a slider (or pull tab) is the locking or nonlocking type. Always be certain that the pull tab is lifted at right angles to the slider before attempting to remove the locking type. The

1115

PR.302

Figure 12-6.—Installing the large curtain type fastener.

PR.303

Figure 12-7.—Installing the glove snap type fastener.

PR.304

Figure 12-8.—(A) Grommets, plain and spur.

relative positions of the pull tabs are shown in figure 12-12.

SLIDE FASTENER TOOLS

In addition to common tools such as screwdrivers, pliers, awls, knives, scissors, and needles, a well-equipped slide fastener kit should be included in the parachute loft equipment.

The slide fastener kit (zipper repair kit) contains all the parts necessary to repair any size or type slide fastener, plus the following special tools: end cutters, or nippers, used for

11116

PR.305

Figure 12-8.—(B) Grommet and washer used on parachute container.

PR.306

Figure 12-9.—Hand press and hand grommet setting tools.

removing stops and teeth; stop-closing pliers, specially designed to span over the slider and clamp the stops in position; and pull-up pliers, designed to close the slider without a pull tab. Another handy tool in slide fastener repair is an awl with a bent tip. This tool may be used to close the chain by hand.

SLIDE FASTENER REPAIR

A torn or ripped zipper cord cannot be repaired, but should be replaced with a complete new slide fastener. If the cord is damaged near the top or bottom of the slide fastener, and the damaged ends can be cut off to shorten the slide fastener without hampering the usefulness of the garment, an effective repair can be made.

Loose or missing teeth and stops will cause trouble. If teeth or stops are not tightened, they will eventually be lost and tear the cord. In repairing such damage, see that the loose stop is in position (almost touching teeth), then set tightly with stop-closing pliers. Set any loose teeth parallel with the other teeth in the chain, then apply pressure with the stop-closing pliers. If a replacement stop is not available in the repair kit, a soft wire or heavy thread may be used as a temporary stop.

A missing tooth should be repaired by replacing the entire slide fastener. However, in the event that there are no spare fasteners available, a missing tooth may be replaced. This is done by carefully removing the stop from the top of the chain, taking off the top tooth, replacing the stop, and setting the tooth in place. (Use caution, do not damage the bead of the chain when resetting the tooth.)

Difficulty may be encountered in moving the slider on the chain. This is caused by the jaws of the slider being too tight, or a dirty chain may be the trouble. To loosen the slider, insert a screwdriver between the jaws, and very gently pry them apart until free operation is effected. A dirty chain is cleaned in the manner described in a preceding paragraph.

TYPE A - NON-SEPARATING, SINGLE ACTION.
TYPE B - SEPARATING, SINGLE ACTION.
TYPE C - NON-SEPARATING, SINGLE ACTION WITH BRIDGE STOP.
TYPE D - SEPARATING, SINGLE ACTION, QUICK DETACHING.
TYPE E - NON-SEPARATING, DOUBLE ACTION, CENTER OPENING.
TYPE F - NON-SEPARATING, DOUBLE ACTION WITH BRIDGE STOP.
TYPE G - SEPARATING, DOUBLE ACTION, END OPENING.

SIZE 0 - LIGHT SERVICE.
SIZE 1 - LIGHT-MEDIUM SERVICE.
SIZE 2 - MEDIUM SERVICE.
SIZE 3 - MEDIUM HEAVY SERVICE.
SIZE 4 - HEAVY SERVICE.

STYLE S - STANDARD NON-LOCKING.
STYLE L - LOCKING.

PR.307

Figure 12-10.—Slide fasteners, inlocking.

Should the slider become jammed with fur, wool, or other material, carefully remove such matter with a pin or needle while gently pulling the slider until it is released. If it is so badly jammed that it resists all efforts, remove the slider by carefully bending the jaws apart and returning the jaws to their original position. The slider is then replaced on the chain, as described later.

Most pull tabs have two small projections fitting into slots on each side of the slider. To remove the pull tab, use two pairs of pliers, one on each side, and twist in opposite directions. In replacing pull tabs, this procedure is reversed. Pull tabs furnished as replacements need only to be squeezed onto the slider.

In making repairs to a damaged slider, the slider must be removed. The proper procedure for removing and replacing a slider on the chain following repairs is explained in the following paragraphs.

To remove the slider from the regular type slide fastener (nonseparating), carefully rip the stitches from the BOTTOM of the slide fastener to expose the ends of the tape. Then remove the bottom stop, and slip the slider off the bottom of the chain and entirely off the cords and tape, as shown in figure 12-13.

To replace the slider on a regular type slide fastener, thread the two bottom cords into the wide end of the slider. Hold the tape so that the bottom teeth are correctly matched, then draw the slider upward until the teeth mesh for several inches. Without allowing the teeth to separate, clamp the bottom stop close to the teeth and over both cords. Replace the tape ends and ripped stitches by hand or by machine.

To remove a damaged slider on a separating type slide fastener, carefully rip the stitches at the TOP of the slide fastener, on the retainer side only, thus exposing the end of the tape. Remove the top stop, slip the slider off the top of the chain, and completely remove it from the cord and tape. Repair or replace the slider.

To replace the slider on a separating type slide fastener, thread the cord on the retainer side into the narrow end of the slider, and allow the slider to slip down the chain. Replace the tape end and ripped stitches by hand or machine.

To replace the slider on the top of a regular, nonseparating type slide fastener with the aid of pull-up pliers, slip the tool over the bottom stop, clamp together, and pull upward. Close the entire chain in this manner. Thread the two top cords into the narrow end of the slider, holding the teeth meshed until they enter the slider. Replace the top stops, tape ends, and ripped stitches.

11118

PR.308

Figure 12-11.—Slide fastener parts.

PR.309

Figure 12-12.—Slide fastener pull tabs.

Shortening a Slide Fastener

To shorten a slide fastener, first determine the length required. The chain should be about 1/2 inch shorter than the opening in the material or garment. Mark the desired length, measuring from the bottom stop upward. Open the chain to any point below this mark and cut directly across the tape about 1 inch above the mark. Cut the excess teeth from the marking point to the end of the tape, and replace the two stops, crimping them firmly.

Installing a Slide Fastener

The installation of a slide fastener will vary with the type of job. Some will be curved, some around corners, and some hidden. The installation of a straight slide fastener is illustrated in the following paragraphs.

Slide Fastener Presser Foot

In order to install a slide fastener neater and easier, a slide fastener presser foot should be used on the sewing machine. The slide fastener presser foot will serve not only as a guide for a neat row of stitches, but will also prevent the foot from riding up on the chain.

The sewing machine manufacturer can supply a regular slide fastener presser foot (right or left) for any sewing machine, or one can be made locally. File or grind the left side of an old presser foot to permit sewing to within 1/8 inch of the chain.

Fabrication

When sewing, always stretch the slide fastener and not the material, as this makes a flatter and neater job.

A simple method of installing a slide fastener when making a bag or cover with two closed ends follows: Lay the piece of material

11119

PR.310

Figure 12-13.—Removing the slider.

right side down, and place the slide fastener right side down on top of the material where the opening is to be located. Sew a row of stitches completely around the outer edge of the tape, as shown in figure 12-14.

Turn the material over. Then by feeling with the points of a pair of scissors, cut the material directly down the center of the chain and cut a V at each end, as shown in figure 12-15.

Turn the edges of the material under, thus exposing the chain. Allow sufficient space between the chain and the folded edge of the material, to prevent the slider from rubbing the edge of the hems. Cutting the V at each end of the chain permits the sewing of neat, square corners. (See fig. 12-16.)

PR.311

Figure 12-14.—Installation of a slide fastener. Step 1.

PROCUREMENT OF SLIDE FASTENERS

The nonseparating slide fastener tape chain is stocked in bulk rolls of 10-foot minimum lengths in sizes 1 and 3. They are interlocked while carried in stock and will remain interlocked when shipped. The unit of issue is in feet.

The separating slide fasteners (with retainers and separating pins attached) are stocked in size 3 only, and in lengths of 24, 48, 72, and 108 inches. Unit of issue is EACH. Necessary stops and sliders are stocked in bulk. Only the style L, locking, nonreversible, single pull slider is furnished.

Size 1 medium service and size 3 extra heavy service fasteners are the only two sizes in stock.

Activities should specify the brand of chain for which stops and sliders are required. (Talon, Crown, or any other make.)

Slide fasteners in stock will be supplied in the nearest length ordered. When received, the chain should be cut to the desired length; stops can be salvaged and reused on the cut chain.

VELCRO TAPE FASTENERS (MIL-F-21840)

Velcro is a tape fastener constructed of woven nylon material. The assembly consists of two sections of tape, one composed of hooks and the

114120

PR.312
Figure 12-15.—Installation of a slide fastener. Step 2.

PR.313
Figure 12-16.—Installation of a slide fastener. Step 3.

other of pile loops. The hook tape contains a multitude of miniature nylon filaments woven in the form of raised loops which can be heat set to retain their shape and cut near their outer edges in order to form a hook engaging section.

The pile tape of the fastener contains a myriad of tiny, soft loops, woven of nylon threads, suitably napped to form a uniform disorientated pile surface of uncut loops capable of being engaged by the hooks of the hook tape component. (See fig. 12-17.)

A closure of the hook and pile tape can be completed by mating the two tapes and applying a slight pressure which forces the hooks into the loops of the pile causing the tapes to adhere to each other. The fastener can be opened easily by peeling apart the two tapes.

A Velcro nylon tape fastener, when properly engaged, forms a versatile, adjustable, and secure closure. It has the ability to distribute equal stress over an entire surface area.

INSTALLATION

The installation of Velcro tape will vary with the type job. It can be applied to other materials or fabrics by using approved cements or by stitching.

In the application of Velcro tape fasteners, always refer to the applicable directives concerning type of thread, stitches per inch, width, and type of Velcro tape required.

11121

of the thyratron switch tube through the d-c blocking capacitor C402. When triggered the switch tube ionizes and provides a closed circuit for the discharge of the pulse-forming network. This discharge continues for a definite period of time at a constant rate, determined by the constants of the pulse-forming network. A negative square-shaped pulse is impressed across the primary winding of the magnetron pulse transformer T404. The width of the transmitter pulse varies in a manner determined by the number of sections of the pulse line in use, as determined by the long-range pulse relay K404. Since the primary of transformer T404 is matched with the 50-ohm surge or characteristic impedance of the pulse-forming network or line, there is an equal division of voltage between these two units. Approximately 2,500 volts is impressed on the primary of T404. The turns ratio of T404 causes a voltage step-up of 1 to 5. Thus a negative pulse of approximately 12 kilovolts is placed on the cathode of the magnetron V406. The peak power of this pulse is in the order of 150 kilowatts. Output of the magnetron approximates 50 kilowatts due to losses in this tube and the associated circuits.

Gas bursts (arcing) occur occasionally within the magnetron. This condition causes momentary pulse-transformer impedance mismatching, and a small voltage of polarity opposite to that of the modulator pulse may appear across the pulse-forming network after the pulse. This small reverse voltage is in series with the power supply voltage at the start of the next charging cycle. Hence the total voltage available to produce the charging oscillation is increased, and the pulse-line voltage may build up to a value great enough to break down the thyratron. This condition is overcome by connecting inverse diode V404 in parallel with the thyratron. The diode bypasses the reversed charge of the pulse-forming network.

The pulse-forming network is composed of aircore inductors and mica capacitors. It is divided into two sections of artificial transmission line, all within the same container. Each part is a complete network. The connection of the two parts by relay K404 increases the width of the pulse. When only the first section Z401-A is in use, 0.75-microsecond pulses are generated. Addition of the second section increases the pulse period by 4.25 microseconds. With both sections connected, pulses of 5.0-microseconds duration are generated.

During long-range search operation relay, K404, is energized; thus both sections of Z401 are connected in the circuit to provide a 5.0-microsecond pulse.

Resonant charging choke L401 not only doubles the pulse-system voltage before firing, but it effectively isolates the power supply from the rest of the modulator during the relatively short periods of pulse duration. It also prevents the power supply from shorting through the switch tube during de-ionization.

Resistor R407 functions as a grid leak for the thyratron switch tube. Capacitor C403 and choke L402 form a filter network to prevent the reflection of the switch tube transients into the synchronizer. Switch tube current, flowing through the cathode resistor R408, generates a trigger pulse which is used for synchronizing the range mark start-stop multivibrator located in the synchronizer. Resistor R409 and capacitor C413 improve the trigger shape by removing ripple at the top of the pulse.

The cathode of the magnetron is internally connected to one side of the filament line. Input to the magnetron is applied by the modulator through the magnetron pulse transformer T404. The design of the pulse transformer provides two secondaries of similar electrical characteristics, one in each leg of the magnetron filament supply. This bifilar secondary winding maintains an equal and in-phase pulse voltage on both sides of the filament and effectively isolates the high-voltage modulator pulse from the low-voltage magnetron filament transformer T405. Capacitors C406 and C405 compensate for slight electrical differences between the pulse transformer output windings to prevent the appearance of high pulse voltages across the filament.

The d-c plate current of the magnetron flows through the cathode circuit of V406, pins 3 and 5 of the pulse-transformer, L404 and the 220-ohm resistor R411. Coil L404 (1 millihenry) blocks peak pulses but passes average current through the magnetron current meter. Capacitor C404 offers a low impedance to magnetron pulses and integrates them for metering. Negligible current is generated within the magnetron during quiescence, but the average of d-c current summed over a period of pulsed operation is of high magnitude. Longer pulse periods at lower PRF tend to balance shorter pulse periods at higher PRF, resulting in a nearly uniform duty cycle regardless of the radar function being performed. Note that while 115-volts is applied to the magnetron filament transformer during

Orig.

TYPES

Velcro tape is available in the following two types:

Type I—0.0065 inch monofilament diameter.
Type II—0.0080 inch monofilament diameter.

WIDTHS

The range of widths of Velcro tape is as follows:

Five-eighths inch.
Three-fourths inch.
1 inch.
2 inch.

PROCUREMENT

Velcro tape may be requisitioned through normal supply changes. The hook and pile tapes are packaged separately and may be ordered individually.

PR.314
Figure 12-17.—Hook and pile tape fastener.

11122

CHAPTER 13

PROTECTIVE HELMETS AND OXYGEN MASKS

PROTECTIVE HELMETS

The wearing of protective helmets during takeoff, flight, and landing by pilots and aircrewmen is required in designated types of aircraft. Helmets are constructed to distribute impact forces over the entire head and to absorb much of these forces so that a minimum amount of shock reaches the skull and brain.

Helmets have long been accepted items for head protection in athletics and certain hazardous industries. They have also been in long use in naval aviation. In early days, aviation helmets were of the same type as motor cyclists' helmets, designed primarily to give protection against windblast. Later, they were made similar to football helmets with the idea of protecting against impact. However, with advances in aircraft design and speed, the need grew for helmets that would simultaneously provide many types of protection. The advent of high-speed jet aircraft, in particular, emphasized the importance of protective helmets that would effectively reduce the likelihood of concussion of unconsciousness due to in-flight buffeting, crashing, or seat ejection.

One of the main differences between the aircraft protective helmet and the athletic type helmet is in the constituent materials. The aviation crewman's helmet is designed more for absorbing energy than for deflecting energy. Thus, in case of a very heavy blow, the helmet will absorb much of the force of this blow by partial destruction of the material of the helmet rather than by passing the force on the head. This is often important in preventing serious or fatal head injuries, as demonstrated in a number of cases in which the great forces involved damaged the helmets but left the wearers without serious injury. Another way in which the helmet prevents or reduces injury is by spreading the force of the blow over a large area of the skull instead of letting it be concentrated at the point of impact.

TYPE APH-5 PILOT'S PROTECTIVE HELMET

The APH-5 protective helmet is shown in figure 13-1. The helmet is available in large and medium sizes. The complete unit consists of an outer shell, energy-attenuating liner, sizing pads, integrated visor, earcup assemblies, communication cord, oxygen mask retention devices, nape strap, and adjustable chinstrap. Furnished with the unit is an envelope containing four shims and two screws for horizontal adjustment of the earcup assemblies. A sizing instrument, to be utilized in fitting the helmet properly, is issued with each new helmet.

The outer shell provides force-distribution and penetration-resisting properties. The outer shell is molded from glass fabric and a polyester resin.

The liners are provided to absorb or dissipate impact energy and thus minimize skull fracture or brain injury, or both. The three sections of the liner are made of cellular polystyrene sheets and molded to fit closely the inside contours of the outer shell.

The sizing pads permit fitting of the APH-5 helmet to an individual's head contour with the proper balance between stability and comfort. The sizing pads are supplied in three basic configurations—back, crown, and front; also in two basic thicknesses—thin and thick. The pads are miniature size and leather covered, reducing the discomfort that could result from internal heat in the helmet.

The integrated visor provides protection from sunglare, windblast, dust, foreign particles, and flash fires. It has excellent optical properties and resistance to cracking, and when in the UP position is protected from damage by

SSII 11123

PR.315

Figure 13-1.—Type APH-5 pilot's protective helmet.

a housing. The housing is molded from a glass fabric and a polyester resin, similar to the outer shell.

Three colors of visors—clear, tinted, and gold—are available for use in the helmet assembly. The gold colored visor is used for additional eye protection against nuclear flashes. The tinted visor is currently supplied in various densities. This range of densities satisfies various requirements for specific visual conditions and/or individual preferences.

The relative darkness or degree of visible light transmittance is indicated by white markings on the inside edge of the visor. This

611124

marking can be seen more readily by removing the visor from the housing. Table 13-1 shows the markings and the percentage of light transmittance.

Due to manufacturing processes, it is impractical to control transmission of the various filter visors produced. In view of this practice, medium and large size visors with varying percentages of light transmittance are carried in the supply system under a single stock number. It is recommended that personnel check lenses at the squadron level, obtaining individual preferences before procuring from supply.

The earcup assemblies contain the earphones and improve radio reception by providing attenuation of outside noise. Each assembly consists of a phone housing of cellular polystyrene, an ear cushion assembly composed of a soft neoprene foam rubber body, and a diisocyanate foam face cushion. Later models have soft leather covered cushions. If the earcup assemblies are loose and need adjustment, the four shims and two screws contained in the envelope should be utilized to accomplish the lateral adjustment. Proper fit of the earcup is necessary for proper radio reception. The earcups have been designed with a large ear cavity to minimize the possibility of pressure discomfort of the ear. A vinyl film washer is inserted between the earcup and the shell to increase stability of the earcup assembly in the event that the shims are not necessary for lateral adjustment.

Table 13-1.—Visor marking and percentage of light transmittance.

Marking	Percentage of light transmittance
XD1	8 to 10 percent (medium dark)
XXD	6 to 8 percent (dark)
XXX	5 to 6 percent (very dark)
*D	10 to 20 percent
*XD	Under 10 percent

*In the initial quantity of helmets issued to the fleet, these two types of tinted visors were installed.

The communication cord is designed to provide electrical connections between the earphones and the aircraft radio facilities. The molded junction block connecting the four earphone leads to the cord is located in the back left center of the middle section of the cellular polystyrene energy-absorbing material.

The installation of the boom type microphone, when desired, should be accomplished as follows:

Pre-position the boom mike assembly on the side of the helmet. Swing the boom through a full arc to determine the best position for attachment of the mounting bracket. Then scribe the intended position of the bracket mounting holes, drill holes accordingly, and attach. The position will vary with the face shape and personal preference. Boom type microphones are not provided with the helmet assembly and must be ordered individually.

Type H-87A/U earphones are installed in the cellular polystyrene earcups of the ear cushion assembly. Each earphone is connected to the two wires leading out of each side of the molded junction block of the communication cord.

Fitting Technique

To properly use the sizing instrument and fit the APH-5 helmet for optimum comfort and stability, the following instructions should be applied:

Determine the head length. The helmet size and liner thickness are indicated on the horizontal bar. Determine the head breadth. When the head length dimensions provide a choice between two sizes of helmets, the head breadth should be the factor in determining the proper size. If the head breadth is over 6 inches, use the large size helmet with all thick liners (sizing pads). If the head breadth is under 6 inches, use the medium helmet with all thin liners.

After the liners have been inserted, have the pilot don the helmet. The proper way to don the helmet is to place the thumbs over the ear cushions, and pull outward on the helmet; insert the forehead in the area between the thumbs, and complete the donning by rolling the helmet backward until it is positioned satisfactorily.

COMFORT.—If the helmet is not comfortable to the pilot, make the following suggested revisions:

If a thick liner is used in the area affected, substitute a liner of lesser thickness. If the pressure point remains, choose the next larger

11125

size helmet and use the thick liners in the unaffected area and the thin liners in the affected area. Earcups can be modified slightly by filing a portion of the outer edge of the attaching side away to relieve pressure points and improve comfort.

STABILITY.—To obtain maximum stability, a snug fit is required. It is possible that stability has been sacrificed for comfort in relieving the pressure points. Proper stability can be determined by vigorously shaking the head. Keep in mind that the pilot must be the judge in determining the correct balance between comfort and stability of the helmet.

After the fitting has been accomplished and sufficient flights have been made to determine adequacy of fit, the unused sizing pads, shims, and sizing instruments should be returned to the local supply for reissue. In addition, clear visors that are not being used should be returned to supply for reissue.

Maintenance

There is a minimum amount of maintenance on the helmet, since the pilot keeps it in his possession. On occasions, maintenance such as recementing loose sizing pads, liners, etc., may be necessary. When not in use, the helmet should always be kept in the bag provided.

CHANGING THE VISOR.—Changing the visor on the APH-5 helmet is a simple task, but the following procedure should be followed:

Place the visor in the down position and remove the locking screw from the visor lock (the locking screw has a left-hand thread), then remove the adjustment knob (right-hand thread) and clamping washer. Turn the key assembly 90 degrees and lift out of the track slot, then remove visor from visor housing.

To insert a visor replacement, this procedure is reversed.

CLEANING THE VISORS.—The following procedure for cleaning visors is recommended:

Wash the visor with mild soap and water, using a clean soft cloth. If the visor is still soiled or if it is necessary to remove minor scratches, use polish. Specification MIL-C-18767B polish is used on acrylic plastic. To preserve the surface, use polishing wax for the final application.

REPLACEMENT OF ELECTRONIC EQUIPMENT.—To replace the communication cord, remove the ear cushion assembly from the helmet by removing the screw on each side of the outer shell. The earphones can be disconnected from the wiring harness after the ear cushion proper has been removed from the polystyrene housing. At this point, release the screw engaging the clip and junction plate at the rear portion of the helmet for complete removal of the communication cord.

To replace the communications equipment, reverse the above procedure.

Installation of the Hardman Oxygen Mask Retention Kit

The Hardman 3740 oxygen mask retention kit is provided for attaching the A-13A oxygen mask to the APH-5 pilot's protective helmet. Installation of this kit affords greater retention of the mask and helmet during high-altitude/high-speed bailouts. Instructions for installation are provided with each kit.

OXYGEN MASK AND HELMET MODIFICATION.—Before attempting to install the retention kit, make certain that the oxygen mask and the kit are of the same size. Remove all the straps and the metal yoke from the mask. Cut off the protruding rubber strap attachment loops from the mask. This is done by cutting flush at the mask surface with a sharp knife or a pair of end cutters. Remove the lip strap supporting the sealing flanges of the mask. (The removal of the lip strap is optional for comfort.) Place the stripped oxygen mask in the retainer shield assembly.

Remove the earphone assembly, the oxygen mask leather tabs, and chinstrap from the helmet.

ADJUSTMENT TO PERSONNEL.—Locate a point 1 1/8 to 1 1/4 inches below the end of the visor track and 1 to 1 1/8 inches back of the forward edge of the helmet, as shown in figure 13-2. Drill a 3/16-inch diameter hole at this location.

Place the backing plate on the inside of the helmet and the latch assembly on the outside of the helmet. Insert the long screw with lockwasher into the alined hole from the backing plate. This screw is tightened until friction against the helmet will hold the latch assembly in place. This step is repeated for the opposite side. Reinstall the earphone assembly.

Don the helmet and insert the bayonets to the third notch. Adjust the straps to provide uniform tension and proper positioning of the oxygen mask to the face.

11126

Adjust the latch assembly by rotating on the screw, either up or down as required, lining up the bayonet centerline with the latch assembly centerline, as shown in figures 13-2 and 13-3. This provides proper distribution of tension required to support the oxygen mask and facilitates proper release characteristics. If tension is evenly distributed between the two straps on either side, the bayonets should release with no binding tendency.

After proper positioning of the latch assembly, remove the oxygen mask and mark or scribe the location of the three additional mounting screw holes. Remove the earphone assemblies, backing plate, and latch assembly, and drill the additional holes 3/16 inch in diameter. Secure the backing plate assembly, and reinstall the earphone assemblies.

Insert the bayonet fittings to the third notch. Tighten the four adjustable straps to provide a snug fit of the oxygen mask. Maintain equal tension on all straps. When the mask has been adjusted for normal wearing, two additional steps for increasing tension are actually available since each bayonet can be tightened independently another notch.

APH-6 PILOT'S PROTECTIVE HELMET

The APH-6 helmet was designed for use by pilots and aircrewmen while flying in fixed wing aircraft.

The APH-6 serves the same function as the APH-5 with the following improvements:

1. An additional size of sizing pad—extra thin—is provided.

PR.316

Figure 13-2.—Alinement of the latch assembly.

2. The oxygen mask suspension system is an integral part of the helmet (the Sierra fitting is built in).
3. Edgeroll is thinner and made of rubber.
4. This helmet comes equipped with the new Shepard visor lock.
5. The visor may be removed without removing the visor housing.
6. The chin and nape strap have coverings for protection of the skin against chafing and for improved comfort to the wearer.

The APH-6 protective helmet is shown in figure 13-4.

The APH-6 is available in medium and large sizes. With modular requisitioning, the basic APH-6 helmet may be updated to the following three present models:

1. APH-6A has the improved visor tracks and earcup suspension.
2. APH-6B has the addition of sonic earcups.
3. APH-6C, dual visor adaptation.

SPH-3B PILOT'S SOUND PROTECTIVE HELMET

The SPH-3B helmet is designated as standard for use by helicopter pilots and aircrewmen. The type SPH-3B helmet is furnished in two sizes, regular and X-large. When properly fitted and adjusted, it provides the lastest in comfort and sound attenuation.

The helmet features a dual visor and provides impact protection and support of terminal communications equipment. The SPH-3B helmet is shown in figure 13-5.

The SPH-3B helmet suspension system (3 crown straps) must be adjusted to allow the head to set as far back as possible into the helmet without interfering with vision and without the crown of the head touching the energy absorbing liner.

All three crown straps, when properly adjusted, should show the same tension when the crown pad is pressed in the center, as shown in figure 13-6.

The earcup tension straps and the chin strap should be adjusted in conjunction with spacers and the sizing pads to produce a secure fit without discomfort. The sizing pads are supplied in four thicknesses (1/4", 1/2", 5/8", and 3/4") and are attached above the nape area. Use one thickness as required and mate the hook and pile tape firmly for a secure installation.

11127 38111

PR.317

Figure 13-3.—Alinement of oxygen mask straps and bayonets.

The nape strap may be tightened with the helmet on by pulling on the free end. To loosen, raise the protrusion on the buckle and pull the secured end. Tighten the nape strap to provide a snug fit with the chin strap fastened.

Proper helmet fit and stability can be checked by shaking the head rapidly sideways with the helmet secured as for normal flight. There should be no significant motion between the helmet and the head.

The visors may be locked at any position which suits the wearer, provided that a reasonably close fit is achieved between the visor and the facial contours. The nose indent of the visors may be carefully sanded or filed to adjust to individual contours.

Visor cleaning may be accomplished using a mild soap and water and a soft, clean cloth. For removal or minor scratches, use acrylic plastic cleaning and polishing compound.

OXYGEN MASKS

Oxygen masks are the final link in conveying oxygen from the aircraft system to the user. A satisfactory regulator and oxygen system or a full cylinder of oxygen is of little value to a pilot if his oxygen mask is not operating properly in every respect.

Oxygen masks are pilots' personal equipment; that is; after initial fitting, they are retained by the individual to whom issued. Fitting, adjustments, maintenance, cleaning, and incorporating modifications are the responsibility of the PR.

The important factor to remember about identifying any oxygen mask is its compatibility with the oxygen system with which the mask is to be mated.

Three types of oxygen masks are discussed in this chapter. They are the PRESSURE BREATHING MASK, the DEMAND OXYGEN

11128

PR.318

Figure 13-4.—APH-6 helmet (side view).

PR.319

Figure 13-5.—SPH-3B helmet.

MASK, and the SMOKE and FULL FACE OXYGEN MASK.

PRESSURE BREATHING MASK

The pressure breathing mask used in the Navy is designated as the A-13A. This oxygen mask is used with composite diluter demand systems, with straight diluter demand systems (with no emergency valve), with automatic positive pressure diluter demand regulators, or with the miniature positive pressure 100 percent demand mask or chest mounted regulator.

The A-13A oxygen masks currently used are satisfactory for flights up to 50,000 feet altitude without regard to service life if properly maintained. The incorporation of the laminate seal (described later) improves fitting and comfort of the mask to the face.

Construction

The A-13A pressure breathing oxygen mask consists of a facepiece, inhalation valves, pressure compensating exhalation valve, microphone cavity, harness assembly, and breathing hose

11130

PR.320

Figure 13-6.—Suspension system adjustments.

assembly. It has two cheek flaps that protect about half the face.

The A-13A mask is supplied in sizes small, medium, and large. The mask should be selected to fit the facial features of the user.

With the exception of the retention assembly, suspension straps, and laminated face seal, the A-13A mask is molded from Buna-N rubber stock, medium green in color. This stock is compounded to resist mildew and remain flexible at a low temperature.

The A-13A silicone pressure breathing mask is constructed of elastomer materials, has a dark olive color, and is made in three sizes. The A-13A silicone mask has a longer shelf life, contains ozone resistant properties, is free of odor, and causes less facial irritation.

The inner parts and mask components are the same as all A-13A oxygen masks. Due to the make of this mask the laminar seal does NOT need to be installed.

Operation

When a flow of oxygen under pressure is supplied to the mask, the pilot must exhale at a pressure greater than that of the oxygen intake, in order to open the pressure compensated exhalation valve and complete the breathing cycle. Figure 13-7 illustrates the operation of the A-13A mask with the diluter demand system; figure 13-8 illustrates the operation of the mask with the pressure breathing system.

The inhalation value assembly is composed of a plastic valve seat, silicone flapper, silicone valve gasket, and plastic cover. The oxygen passes through an inlet hose attached to the inlet port of the mask. The oxygen is then fed through the inlet port to the interior of the mask through two inlet ducts, one on each side of the mask. The inhalation check valves prevent the exhaled air from passing back through the inhalation ducts of the facepiece. A plastic cover eliminates the collection of moisture around the valve where it may freeze under extremely cold conditions and directs the flow of incoming oxygen within the mask.

The pressure compensating exhalation valve (fig. 13-9) fits into the exhalation valve cavity of the mask and the valve stem extends through an opening in the wall that separates the exhalation port housing and the inlet tube. This arrangement permits the open end of the valve stem to be exposed to the oxygen as it passes from the inlet port into the facepiece. The stem of the exhalation valve brings oxygen pressure to bear against the lower side of the compensating diaphragm (15). This pressure, plus the pressure of a calibrated spring, causes the diaphragm to close the valve. In this position, no oxygen can escape from the facepiece.

As the pressure in the facepiece is increased against the main diaphragm (10), because of exhalation of the wearer, the combined pressure in the inlet port and the calibrated spring is overcome, and the valve opens. Exhaled air (9) escapes from the exhalation port at the bottom of the facepiece. The valve is constructed so that a pressure of only 1 millimeter of mercury greater than that of which is being supplied by the regulator will force it open.

Microphone Installation

The ANB-M-C1 microphone used with the oxygen mask is drawn from supply by the pilot at the time he draws his oxygen mask and other personal flight gear. The original installation of the microphone is the responsibility of the PR. The repair of any reported malfunctions and modifications is the responsibility of the avionics division and is to be performed by electronics technicians.

Before installing the microphone, disassemble the mask and clean the facepiece and corrugated hose in a solution of mild soap, Specification MIL-C-18687 and warm water.

UCII41131

standby it is reduced to 65 volts when the high voltage is applied to the modulator.

IMPEDANCE MISMATCHES

The function of the radar antenna system is to direct the RF energy pulses from the transmitter to the antenna array, radiate this energy in a directional (or nondirectional in some applications) beam, receive the returning echo, and direct it to the receiver with a minimum of signal loss. The radar antenna system includes the RF transmission lines (couplers, junctions, rotating joints, radiating collector array, and protective devices) from the transmitter and receiver to the antenna array. To insure efficient performance with minimum loss, the antenna systems are carefully engineered and must operate within specified limits. Improper coupling between RF lines and the antenna or transmitter, for instance, may produce an impedance mismatch resulting in a high voltage standing-wave ratio (VSWR) and a general reduction in system performance.

The VSWR is measured to insure that the ratio of the power transmitted by the magnetron to the power reflected back along the transmission line is within the specific limits. Any discontinuous change along an RF line, such as a sudden change in dimensions, a change in geometry introduced by a sharp bend or dent, or an obstacle in the line will produce a mismatch resulting in a high VSWR.

If trouble in the RF transmission line (between the magnetron and the antenna) is indicated, adjustment of the magnetron tuning control should be made observing whether this improves the VSWR. If it does not, then determine if the trouble is on the antenna or transmitter side of the antenna switch (duplexer) in the following manner: With the magnetron operating into a dummy load, observe the VSWR. No marked improvement indicates that the trouble is on the magnetron side of the antenna switch, while a marked improvement indicates that the trouble exists on the antenna side. If an increase was noted in the VSWR, check the RF transmission lines for any of the common causes listed below, and for any other damage which might have occurred. Check the antenna also, since any bending in the antenna array could change its impedance and result in an increased VSWR.

Many RF transmission-line faults are visible and easily located; however, in some cases the trouble may be of such a nature that the defective part can be found only by making special tests.

Some of the most common causes of an excessive high VSWR are:

1. Moisture in the RF line.
2. Dented or bent line.
3. Burrs or poorly soldered joints.
4. Defective coupling joints.
5. Defective or distorted rotating joints.
6. Mismatched antenna.

TRANSMITTER SAFETY DEVICES

Generally, transmitter protection is present in four areas of the transmitter. These areas are the magnetron filament control circuit, modulator high voltage control circuit, transmitter overload circuit, and transmitter metering circuit.

Magnetron Filament Control Circuit

The purpose of this circuit is to allow the magnetron filament to reach the proper operating temperature prior to the application of a high voltage pulse from the modulator. The circuitry may vary from the simple time delay relay to the complex circuitry of some radar sets.

Modulator High-Voltage Control Circuit

In case of interlock failure or overloads, the primary power control is driven beyond the minimum voltage position which in turn opens a safety limit switch and the modulator voltage is removed.

Transmitter Overload Circuit

This circuit is designed to remove modulator primary power when either an excessive modulator current exists or whenever excessive reverse current flows through the reverse current relay. A manual reset circuit restores the operation of the transmitter.

Transmitter Metering Circuit

This is a visual safety system which indicates by lights and meters, magnetron filament voltage, magnetron plate current, modulator current, transmitter overload, operation of the

7. Plates which stiffen the main diaphragm.
8. Projections on valve housing which seat in mask.
9. Exhaled air leaves the valve here.
10. Main diaphragm.
11. This port permits pressure between the two diaphragms to equalize with the outside atmosphere.
12. Cup which holds hairspring in place between the two diaphragms.
13. Oxygen supply pressure is exerted in this compensating chamber.
14. Exhalation valve stem.
15. Compensating diaphragm.

PR.323

Figure 13-9.—Cutaway of pressure-demand mask and exhalation valve details.

Remove all traces of any white granular substance which may be present in new masks. If not removed, an excessive amount of these tiny granules can become trapped under the rubber flaps of the inhalation valves thereby preventing a perfect seat. The inhalation valves and their rubber valve flaps must be perfectly seated to prevent an equalizing back pressure into the mask tube. Such a condition will prevent use of the exhalation valve.

Before installing the exhalation valve, clean it, removing dirt and dust particles that lie between the diaphragms and their contacting seats. Particles of dirt trapped under the diaphragm can prevent the exhalation valve from closing off, thereby permitting outside air to be drawn in, diluting the the oxygen. Dry and reassemble the mask with the exception of the inhalation valves. Leaving the inhalation valves out of the facepiece until after the microphone is installed makes it easier to install.

The steps required for the installation of the ANB-M-C1 microphone are as follows:

1. Remove the microphone cord "hole plug" by pulling it out at the front of the mask. Lubricate cord with soap solution.

2. Pass the microphone cable through the rubber guide at the front of the mask.

3. Insert tapered long nose pliers through mike cord hole from the inside of the mask; tips of the pliers must show at least 1/8 inch beyond the outside edge of the hole.

4. With the pliers opened slightly, just enough to permit a sure grip on the outer diameter of the cord, insert the end of the microphone cable through the elongated hole. Handle the pliers carefully in order to avoid tearing the hole and the rubber bridge piece joining the inner mask lips.

5. Once the outer diameter of the microphone cable has been grasped by the pliers, do not loosen the grip until the cable has been drawn through the hole. Loosening the grip while drawing the cable through the hole usually results in a second unseen grip on the frail terminal wires with subsequent damage to the cables and/or terminal ends. Pull enough cable up into the mask to gain an adequate length for connecting the terminals to the microphone.

6. Remove the microphone from its plastic adapter by unscrewing. This plastic case and case cover are of no further use as they are not inserted into the microphone cavity of the oxygen mask. Remove the three connections from the back side of the microphone.

11123

7. Attach the wire terminals to the microphone with the lockwashers beneath the terminals.

8. After the terminals have been connected, draw the mike down to its cavity in the forward position of the oxygen mask. Do not pull the cord abruptly, and stop the pulling action when the mike is flush with the rim of the cavity.

9. Using a blunt instrument (such as a pencil eraser), work the mike into its cavity slowly and progressively. CAUTION: Do not press on plastic portion of mike, press on metal edge. When a part of the mike has been entered into its seat, pull out more of the surplus cable. When doing this, be careful not to break the terminal connections. Completely seat the mike in its cavity.

10. Being exceptionally careful, pull out all the remaining surplus cable and remove the slack between the guide and where it emerges from the hole.

11. Replace the inhalation valves and covers, making certain that the arrow on the covers are pointing downward. If the inside surface of the plastic covers have not been scored, preventing the rubber valves from sticking to them, comply with the latest NavAirSysCom publication referencing the modification. All newly manufactured inhalation valve covers will already be modified, making the field change unnecessary.

12. Place the oxygen mask to your face and check for leakage around the hole where the microphone cable enters the mask. Test the breathing action of the mask on a mockup system, using safety pressure.

13. Have the installed microphone BENCH CHECKED by the avionics division, making certain that it will work properly.

Testing and Inspecting A-13A Mask

PREFLIGHT TESTS.—Preflight tests should be made to establish the security of all parts, with special attention given to the inlet check valves and exhalation valve. The plastic shields must be scored on the inside and be snap seated over the inlet valves.

The inlet valves and exhalation valve must be free from dirt and dust particles. A preflight test should be made just prior to each flight by attaching the mask to the pressure-demand regulator installed in the aircraft. The operational check should be under both demand and pressure-demand conditions. In the event any difficulty is encountered, the oxygen mask should be replaced.

Check the mask for fit and minimum mask leakage in the following manner:

1. Adjust the mask securely in place and connect the mask to the regulator breathing tube.

2. With the oxygen system turned on, place the regulator safety pressure selector lever in the ON position. Induce a severe outboard mask leakage by placing two fingers under the mask sealing surface (cheek flaps) and observe the flow indicator. It should remain in the FLOW position.

3. Reposition the mask on the face and after a few respirations, hold the breath and again observe flow indicator. If there is no mask leakage, the flow indicator will remain in the NO FLOW position. If there is any leakage, the flow indicator will assume the FLOW indication position.

4. Adjust the suspension straps until the leakage is stopped.

5. Return the safety pressure selector lever to the OFF position and continue with flight preparations.

MASK HOSE AND FITTING LEAKAGE TESTING.—Affixing the mask assembly to the face with the helmet in place and, using the mask suspension, adjust the strap for a snug comfortable leaktight fit. Attach the MC-3A connector to the oxygen supply and set regulator on 100% oxygen with supply valve off. Inhale sharply and deeply, and hold the inhalation (keep inhaling) as long as possible. If there is no inboard leakage, you will not be able to inhale.

TESTING VALVE ASSEMBLIES.—With both inhalation valves and the compensated exhalation valve installed in the mask assembly, place a clean smooth rubber stopper (size No. 1), in place of the MC-3A connector and perform the following tests:

1. Inhalation Valve: Holding the mask close to the face, but not completely sealed to the face, inhale deeply and then immediately press the mask to the face forming a tight seal and forcibly exhale through the exhalation valve. If the inhalation valves are not closing (sealing) properly, the exhalation valve will not open. If the inhalation valves are seating properly, the exhalation will be smooth and with minimum resistance.

CE111134

2. Exhalation Valve: Place an obstruction (rubberband or equal) under the rubber flapper of one of the inhalation valves in a manner to prevent it from forming a seal. Repeat the testing procedure as described in test No. 1. If the exhalation valve is functioning properly, it will not open when the subject exhales, and exhalation through the valve will not be possible.

Installation of Laminate Seal

This modification must be accomplished on all A-13A oxygen masks, (excepting the silicone type). If a pilot specifically requests the adaptation of the seal on a silicone mask, special silicone cements must be used.

This modification on the A-13A oxygen mask is accomplished as follows:

1. Thoroughly roughen the sealing surface of the facepiece with emergy paper or any other suitable abrasive.

2. Apply an even, medium coat of cement to the rough side of the laminate and to the surface of the mask previously roughened. NOTE: The container of cement should be tightly sealed when not in actual use.

3. Determine the approximate centerline of facepiece sealing surface and centerline of laminate.

4. When applied cement feels tacky, lightly lay the upper nose of the laminate and the mask sealing surface in such a manner that the points of the respective centerlines coincide. Care should be exercised so that the rest of the tacky surfaces do not contact each other until symmetrical alinement is obtained.

5. After alinement is assured, lay the laminate and press tightly against the facepiece and allow to dry thoroughly (approximate drying time 24 hours).

NOTE: If laminate is not positioned correctly, or if a wrinkle has developed in laminate, strip laminate from facepiece. Clean facepiece with solvent and repeat, using a new laminate.

Installation of Mask-Mounted Regulators

In today's high performance aircraft, space and weight are vital factors. One method of solving these problems is through the miniaturization of 100 percent demand oxygen regulators.

It is the Aircrew Survival Equipmentman's responsibility to make certain that these regulators and oxygen masks are installed properly.

Miniature oxygen breathing regulators are mask or chest mounted and used both in flight and bailout or emergency condition. The various types of mini regulators are installed on the A-13A oxygen mask as follows:

1. Firewel 1732 and the Bendix regulator may be mask mounted by disconnecting the corrugated mask tubing from the A-13A mask.

Remove the clamp, tubing, and fiber insert from the mask inlet port.

Connect the oxygen hose to the oxygen inlet port of the regulator, inserting the outlet of the regulator into the mask inlet port. Clamp the regulator to the mask with the hose clamp and replace microphone wire.

2. Firewel 2700 and the Robertshaw-Fulton regulators, mask mounting.

Disconnect the corrugated mask tubing from the A-13A mask, removing the clamp and tubing. Remove the fiber insert from the mask inlet port and connect the oxygen inlet port of the regulator. Install the small end of the elastometer on the regulator pickup tube.

Move the regulator toward the oxygen inlet of the mask and connect the large open end of the elastometer to the exhalation valve pickup tube, making certain these two parts mate.

Position the regulator into the mask inlet, and replace the clamp and microphone wire.

3. Firewel 2700-15M, Robertshaw 226-20004 and 226-20004-3 mini regulator chest mounting.

Loosen the Tinnerman clamp and remove the MC-3A fitting. Thread the locknut (TRU-SEAL) to the redar hose. The Teflon face of the locknut should face the end of the male threaded fitting.

Insert the regulator into the mask hose and tighten the clamp. Insert the redar hose into the regulator.

4. Bendix Regulator 29211C1 and 29211B1 may be mounted by loosening the Tinnerman clamp and removing the MC-3A fitting.

Thread the locknut (TRU-SEAL) to the redar hose. The Teflon face of the locknut should face the end of the male threaded fitting. Screw the right angle elbow into the regulator, positioning the female portion of the elbow so that it is alined with the axis of the regulator.

Insert the regulator into the mask hose, tighten the clamp, and insert the redar hose into the regulator.

After installing any of the above mentioned regulators, the PR must check and test each unit for proper security and operation before issuing them to flight personnel.

AC111135

Safety precautions to be observed when working with oxygen masks and regulators are as follows:

1. Handle all miniature regulators with care.
2. Never connect the regulator to an inlet source greater than 90 psi.
3. Clean regulators with only the approved cleaning solvents or solutions.
4. Remove miniature regulators from masks and bench test every 60 days.

DEMAND OXYGEN MASKS

The A-14A oxygen mask should be used with a demand system not having safety pressure features. It is designed to supply adequate oxygen even during bodily exercise in extreme cold in altitudes up to 37,500 feet. With added precautions adequate oxygen is supplied to 40,000 feet if the mask is correctly fitted.

The A-14A mask assembly consists of a mask body which completely covers the nose and mouth. It is fitted with a rubber exhalation valve of the flutter type. The adjustable straps of the suspension harness are arranged differently in comparison with the pressure type mask. The corrugated mask tube is equipped at the opposite end with a single male connector fitting. Regular snap fasteners (not the three-way snap type) are provided for attachment of the mask harness of the helmet.

The microphone is installed in a cavity similar to that in the pressure mask. Since it was not designed to hold pressure, there are no inhalation valves installed in the open ports of the A-14A mask. The exhalation valve is very simple in construction and is designed to prevent air from entering the mask upon inhalation. This means that the rubber flapper is located on the OUTSIDE of the valve.

A rubber cover, or protector, for the inhalation ports is secured to the inside of the facepiece. It is designed to prevent moisture from entering the ports and/or to prevent the formation of ice in the same vicinity.

There are no inner lips in the A-14A. The exhalation valve, seated in the bottom of the mask, permits exhaled air to flow out of the mask through two ports, one on each side of the mask exterior. One of these ports is larger than the other. The larger one allows inspection of the outer portion of the flutter valve and seating of the valve proper.

The exterior microphone cable duct on the A-14A mask is different from the cable duct on the pressure type. In order to insert the cable in the cavity, the tip of the projecting smooth molded cable duct must be cut off. In doing this, care must be taken not to cut off too much of the tip. Removing an excessive amount of duct will result in a hole too large in diameter to adequately seal itself around the cable.

The A-14A mask is available in four sizes—large, medium, small, and extra small. Maintenance of the A-14A is similar to that given for the A-13A in the preceding section.

Smoke and Full Face Oxygen Mask

This mask is replacing the A-14A oxygen mask in some types of aircraft. The operating principles of the mask are the same as the A-14A. The main difference is that the smoke mask has a full facepiece that completely covers the face. Maintenance of the smoke and full face oxygen mask is similar to that given for the A-14A and A-13A.

CLEANING OF OXYGEN MASKS

Cleaning of oxygen masks must be accomplished as often as service conditions require but not less than once every 2 months. The A-13A (silicone) cleaning must not be less than once every 3 months. After disassembling all removable components, throughly inspect each part for serviceable condition. Use the cleaning compound, aircraft surface, MIL-C-18687.

With the proper mixture of 1 1/4 ounces of liquid compound to 1 gallon of warm potable water, wash the mask facepiece using a clean soft gauze pad or brush. After all surfaces have been wiped or brushed, submerge the entire mask in the cleaning solution and agitate throughly.

NOTE: Do not use alcohol in any form to clean the mask; do not use any flammable solvents or toxicant liquids for cleaning.

Using the approved cleaning solution, wash all mask parts and components with a soft gauze pad or brush. The microphone and MC-34 connector must be cleaned with a damp gauze pad only.

Rinse all parts, after washing with the cleaning solvent, in clean, cold water. Cold water tends to form beads and is easily shaken off. Dry the mask and accessories, selecting a well-ventilated place.

11136

Do not hang the mask in sunlight, and do not use compressed air or oxygen to blow masks dry. The ideal storage temperature is 70° Fahrenheit.

After the mask and all components have dried, assemble the complete oxygen mask and thoroughly test the unit for serviceability.

Sanitizing (Disinfecting)

Oxygen masks that are not on a personal issue must be sanitized after each use, using the solutions discussed in the following paragraphs.

Use 1/4 pint of thimerosal as issued; this is a 1.1000 solution of clear merthiolate and distilled water. Add 25 drops of 10 percent concentration of benzalkonium chloride (MIL-B-36021) to 1 quart of potable water.

Moisten a gauze pad with the solution, squeeze to prevent dripping, and wipe out the interior of the mask exclusive of valves and the microphone.

Wipe the valves and microphone with a clean dry cloth. Place the cleaned, RFI oxygen mask in a bag for reissue.

Safety Precautions

Observe the following safety precautions when working with oxygen masks:

1. Never use a screwdriver on any mask part except the hose clamp.
2. Always use the proper cleaning compound MIL-C-18687 and potable water.
3. Never use oil or grease around oxygen masks.
4. When inspecting an oxygen mask, remember that a life depends on your work.

CHAPTER 14

FLIGHT CLOTHING AND PROTECTIVE EQUIPMENT

In keeping pace with the demands of new developments, articles of clothing worn in flight are becoming more complex. The simple coveralls (light and heavyweight) are used daily in moderate speed and low-altitude flight; however, the conditions experienced during high-speed and high-altitude flight have demanded more than a simple warm covering for the body. Consequently, the nature of flight clothing is progressing into a more overall protective stage which guards against sudden losses of cabin pressure and also maintains an oxygen pressure range necessary to life.

Besides protection from moderate to severe temperatures there are other more complicated elements and conditions to be considered. The attainment of recent higher speeds and higher altitudes has added greater problems to man's efforts to cope with the elements. To combat the danger of a sudden loss of cabin pressure (explosive decompression) and to extend the limit of high-altitude flight, the doctors and engineers of medical research have developed a full pressure suit.

The full pressure suit is designed to enclose the entire body. Its function is to provide 100 percent delivery of oxygen under a slight positive pressure for breathing and also air combined with pressure and temperature control to permit flights in the upper regions hitherto unattainable.

Another item is the antiexposure suit which is worn on all overwater flights in cold regions. The outer rubberized forms of the suit, gripping snugly around the wrists and neck, prevents water from contacting the body. An insulated liner worn close to the body provides the necessary warmth. Without a fully equipped antiexposure suit, a man could not survive in water colder than 32° F. The low limit for a 4-hour exposure with full equipment is about 45° F, and generally antiexposure equipment is required in areas where water temperatures are 59° F and lower.

This chapter is not designed to introduce all of the available articles of flight clothing and protective equipment, but offers instructions on fitting and adjusting those items which need special attention in their initial servicing. The protective helmet must be equipped for stability and be made adaptable to the oxygen mask.

In the initial fitting of clothes, the decisions revolve around the correct choice of fit, which is that of selecting the proper size. However, everyone's measurements do not conform with standard size requirements. In naval aviation, it is the PR's job to make flight and protective clothing fit as nearly perfectly as possible.

Occasionally, pilots and aircrewmen request that additional pockets or slings be incorporated in their flight clothing. However, the practice of arbitrarily attaching a sheath knife to the trouser leg of a flight suit might later endanger a smooth and uninterrupted egression. In addition to the possibility of hampering an individual's movement during escape the suspension lines of the opening parachute might foul in the sheath if it has not been attached properly.

Whatever the requests for modifying flight clothing might be, there are four basic factors which must be considered: First, the weather and climatic conditions under which the article will be used; second, the fit of the clothing, since the comfort element depends not only on the type of clothing but also on the proper fitting; third, appropriateness and safety of the modifications in relation to the purpose of the garment; and finally, the authority for the change.

FLIGHT CLOTHING

It is the responsibility of the PR to keep on hand and issue to pilots and crewmen many

11138

varied articles of flight clothing including flight suits, flight jackets, boots, gloves, antiexposure suits, full-pressure suits, and many other items of survival equipment.

FLIGHT SUITS (NOMEX)

The "Nomex" summer flight suit is a light weight high-temperature resistant flight suit made of polymide synthetic fabric. The color of the suit is olive green.

The Nomex suit never has to be treated or retreated with fire retardant compounds. This suit will not support combustion and will not melt or drip. It is a durable flight suit and is easily washed and dried. Chlorite or hypochlorite bleach should not be used when laundering. The bleach does not affect the fire retardancy of Nomex but over a long period of time has degrading effect on the material.

For cold weather flights, a two-piece winter type flight suit has been developed. This winter flight suit is made with a nylon cloth face, backed with dacron pile, and lined with a fire-retardant cotton fabric. The suit does not protect an individual who is submerged in cold water; however, it should be worn under the Mk 4 antiexposure suit.

FLIGHT JACKETS

The intermediate leather flight jacket is chocolate brown in color and has knitted wristlets and waistband with a moth repellent treated mouton processed sheepskin collar. It has a slide fastener closure, is nylon lined, and is available in seven sizes—36, 38, 40, 42, 44, 46, and 48.

BOOTS

Proper boots or shoes play a vital part in maintaining safety, efficiency, and comfort in any climate. Boots or high top service shoes are usually preferable for use in a survival situation. They afford greater protection from sand and insects, provide more support for walking, and are less likely to be lost during bailout than low quarter shoes.

It is the responsibility of the PR to acquaint himself with all types of flight clothing and especially shoes and boots. This will enable him to use good judgment when teaching aircrewmen as to the best methods and equipment for any emergency situation.

GLOVES

The indoctrination of flight personnel in the proper use of gloves and mittens is also an important responsibility of the PR in charge of personal equipment. Flight personnel should be made to realize that the fingers and hands are more vulnerable to frostbite than any other part of the body, and that frostbite usually results in amputation of the injured extremity. Frequent reference to NavWeps 00-80T-56, Survival Training Guide, will give a background in survival training which will enable the PR to assist with almost any situation.

REQUISITIONING

Requisitioning of flight clothing and protective equipment is a function of the supply officer. Naval and Marine Corps student pilot personnel, naval aviators, naval flight officers (including navigators, controllers, and radar), and flight surgeons in a flight status are eligible to receive any or all allowed items of flight clothing and protective equipment, not to exceed one complete outfit.

One complete outfit of flight clothing consists of the following:

1. Boots, safety flying, for issue to student pilots entering preflight training program.
2. Compass, wrist.
3. Computer, navigation, mark 8 type.
4. Coveralls, anti-g.
5. Coveralls, cotton twill for issue to student pilots when commencing pilot training.
6. Coveralls, landing signal officers', issued to personnel who have been assigned that duty.
7. Coveralls, flying, Nomex.
8. Glasses, sun.
9. Glovers, flying, leather, summer, Nomex.
10. Gloves, winter.
11. Goggles, sun.
12. Headset assembly, radio.
13. Helmet, pilots' protective.
14. Jacket, flight, leather, intermediate.
15. Jacket, flying, very light summer.
16. Kit, signal light, landing signal officers', for issue to landing signal officers.
17. Knife and sheath.
18. Mask, oxygen.
19. Microphone, oxygen mask, with cord and plug.
20. Parachute torso harness assembly.
21. Shroud clutter.

22. Wand, taxi guidance, for issue to landing signal officers.

The above articles of equipment are carried by the supply officer or delegated to an officer in charge of a flight clothing pool. Issues are made directly to the individual concerned and the supply officer or his representative makes an entry in the appropriate columns of the "Flight Clothing Record" of the Aviators Flight Log Book, OpNav Form 3760-31.

When the person is relieved of duty involving flying, he must turn in to the supply officer any flight clothing in his possession. If an article of flight clothing becomes unserviceable for any reason such as damage, wear, or other deterioration, it may be turned into the supply officer or the flight clothing pool and exchanged for a serviceable item.

If any item is lost or missing for any reason, the person charged with custody of the item is required to furnish a Survey Request Report and Expenditure (NavSup Form 154) for the missing item.

Winter flight clothing and flight clothing for nonpilot crewmen are the responsibility of the parachute loft and must be maintained in accordance with the allowances listed in the Section H Allowance List.

Requisitioning of these items is usually made by the senior PR or by another PR designated to handle stores for the aviation equipment division.

Defense Department Form DD 1348 is used by aviation activities both ashore and afloat to requisition material. It is available in card form for mechanized supply activities and in 2-, 4-, and 6-part, interleaved sets for nonmechanized use. Local requirements determine the number of copies to be prepared at nonmechanized activities. Each item of material must be requisitioned on a separate form.

RECORDS AND REPORTS

Records are important for proper accountability of flight clothing and protective equipment, as well as other materials which are assigned to the parachute loft for reissue on a subcustody basis. Other records which must be kept are logging of inspections, recording of modifications, repairs, and changes to flight clothing, protective equipment, and other survival equipment. These include Parachute Record Cards, Parachute History Cards, liferaft inspection data cards, and static load tests of safety belts and shoulder harness. These records are subject to inspection at any time by higher authority and should be kept accurate and up to date at all times.

FLIGHT CLOTHING MAINTENANCE AND REPAIR

Part of the PR job is maintaining pilot's and aircrawmen's flight clothing in a serviceable condition. This requires a good basic knowledge of the principles involved in tailoring. PR's are not expected to construct a suit of clothing from a bolt of material, but are expected to be able to make repairs and alterations to most of the available flight clothing.

What are the basic principles involved in tailoring? The first and major requirement is knowing how to sew by machine as well as by hand. Second, knowledge of the materials used and the construction of the garment in need of repairs is necessary in order for the PR to properly analyze the scope of damage and the steps to be taken in making the repair. Third, he must have the ability to apply this knowledge, which can be accomplished only by practice and experience.

There are many shapes, sizes, and types of clothing which may require repairs. It is therefore impossible to learn everything about tailoring from a textbook. The best procedure is to practice at making patches on scrap material as well as replacing a sleeve or collar on an old garment. In this way, one may become proficient at making neat, durable, and proper repairs.

Flight clothing is rarely damaged to the extent that a yoke or piece in the suit has to be replaced. The most common damages are ripped seams and small tears in the material, both of which are easily repaired. Stitching a seam or applying a small patch is no great task; however, the same principles regarding the similarity of materials apply here as well as to the parachute. Always strive to use identical materials regardless of the type of repair.

WARNING: When making an alteration or repair, do not stitch through electrical wiring, rubber bladders, or other similar appendages incorporated in certain types of clothing.

11140

HAND SEWING

Handstitching is seldom done by a PR but there will always remain a need for a hand-held needle application of stitching. Machines are not always readily available and often lack the flexibility inherent in handstitching. Many areas still exist in which the handstitch is the best approach to a repair or on assembling step. Realizing these possibilities, a PR should know how to make and where to use a number of the fundamental handstitches.

CLEANING OF FIRE-RETARDANT TREATED FLIGHT CLOTHING

For light or moderately soiled flight clothing, an automatic washer of the type found in the home, aboard ship, or commecrial laundry may be used. Any commercial detergent available may be used with fresh water. If salt water is used, salt water soap "Igepon T" or some other salt water detergent must be used. In neither instance is a bleach or alkali builder required.

Flight clothing heavily soiled with oil and petroleum type grease stains must be immersed in a container of clean Stoddard solvent and agitated for approximately 15 minutes. It is then air dried and laundered as for light or moderately soiled garments. If Stoddard solvent does not remove the stain, the following solution should be prepared and used:

Mix one part of solvent emulsion grease cleaning compound conforming to Specification P-C-576A (type I) with 5 parts of Stoddard solvent and agitate. Immerse the garment in the solution and agitate for 15 minutes. Remove the garment from the solution and wring it dry. Rinse the garment for 3 minutes in fresh water at 176° ±5° F and wring dry. It is then immersed in a solution of sufficient washing machine compound conforming to Specification MIL-C-5543 and water to make a watery solution (approximately 1 pound of washing machine compound to 4 gallons of water). The solution is heated to 140° ±5° F, and the garment is then agitated for 15 minutes, removed, and wrung dry. Rinse it for 3 minutes in fresh water at 176° ±5° F, and wring dry. Air dry the garment and launder in soap and water.

NOTE: Stoddard solvent evaporates rapidly and should be used in a well-ventilated area away from all open flames. Avoid prolonged inhalation.

PROTECTIVE EQUIPMENT

Included in this category are the full pressure suit, torso harness suit, anti-g suit, anti-exposure suit, arm retention sleeves, life preservers, and survival kits and related equipment. Many of these items are used in conjunction with a seat ejection system. Although the PR is not responsible for ejection system maintenance, he should be familiar with the principles of operation and understand how certain items of protective equipment are related to the ejection system. A brief description of a typical system is therefore given in the following paragraphs.

EJECTION SYSTEMS

Seat ejection systems currently used in naval aircraft are designed to provide safe escape from the aircraft at all altitudes and speeds. The system described here is used in the RA-5C series aircraft. The Martin-Baker system, used in a number of other aircraft, is described in chapter 8 of this manual.

The RA-5C ejection system consists of the following main components: seat bucket and carriage assembly, an electrical seat adjustment system, a ballistic system, a seat propulsion system, a seat stabilizing chute system incorporating a stabilizing chute separation system, a body positioning and retention system, a seat-man separation system, an integrated harness system, and a survival kit which includes the emergency oxygen supply system, LR-1 raft, and emergency equipment.

The composite disconnect shown in figure 14-1 (A) provides for the connection of pressure suit ventilation air, oxygen, anti-g suit pressurization air, and communications wiring. Manual operation of the emergency oxygen supply is provided by a green ring on the forward edge of the survival kit.

The integrated harness system performs the functions normally accomplished by the parachute harness, lap safety belt, and shoulder harness.

A harness release handle (fig. 14-1 (A)) permits manual release of the integrated harness, harness takeup inertial reel strap, survival holddown fittings, and parachute cable.

A pair of gas actuated ejector pins and a drogue chute static line with an attached cutter provide for drogue chute separation after seat-man separation and parchute deployment. The

11141

PR.324

Figure 14-1.—(A) Ejection seat and related equipment; (B) low altitute escape sequence.

parachute contains a static line ballistic-delay cutter to sever the lanyard after parachute deployment.

The ejection system is operated by pulling the face curtain handle (fig. 14-1 (A)) or by squeezing the handgrips, located on each knee raising frame. The ejection sequence is as follows: The canopy is jettisoned; the occupant's legs and shoulders are positioned; the rocket fires, propelling the seat-man combination to safe recovery. (See fig. 14-1 (B).)

If the pilot initiates his ejection seat, the aft ejection seat will automatically eject prior to the forward seat. The aft ejection seat can be actuated independently of the forward seat.

SURVIVAL KIT CONTAINER

The survival kit container assembly is a two-piece assembly which acts as a container for the survival kit, liferaft and protective cover, emergency oxygen supply, microphone adapter, adapter switch, and related plumbing, clamping, and wiring. The container acts as a cushion in the seat and has a sponge type polyurethane pad bonded to the contoured surface on top of the upper half of the container by a zipper, and the parachute harness is connected to the upper half of the container on both sides.

LR-1 Raft Configuration

The LR-1 liferaft assembly consists of a liferaft, carbon dioxide cylinder, and an inflation valve. The configuration of a packaged LR-1 liferaft assembly, complete with accessories and survival items, will vary according to application. To make up a complete packaged assembly, all required components must be individually requisitioned. The survival items must be packed in either the combination carrying case and equipment container, or in the equipment container, as applicable. The remaining space in the container may be used for specialized equipment deemed necessary for specific environmental or geographic conditons as directed by the Area Operating Commander.

The survival items for the LR-1 assembly must include the following list of equipment: Survival radio, MK-13-MOD-0 distress signals, dye marker, signaling mirror, signaling code card, rations, desalter kit, water storage bag, nylon cord, bailing sponge, Shark repellent, and sunburn ointment.

Both raft and equipment are attached to the upper half by a 25-foot nylon drop lanyard. The upper half of the container is equipped with the emergency oxygen supply.

11142

NOTE: Items included above are considered as typical of a survival kit and deletions or substitutions may be made as directed by area commanders.

Emergency Oxygen Supply

The emergency oxygen supply is contained in the upper half of the survival kit.

The capacity of the bottle for some aircraft is 100 cubic inches while other aircraft use bottles with a 70-cubic inch capacity.

The oxygen supply is controlled by the reducer assembly on the oxygen bottle. It is actuated automatically during ejection or may be actuated manually. The reducer assembly (when actuated) delivers a demand flow of oxygen of 0 to 140 liters per minute at an outlet pressure of 55 to 80 psi.

The components of the reducer assembly are the actuator assembly, relief valve, charging valve and cover, pressure gage, control level, and outlet port. The actuator assembly consists of a release pin, manual lanyard and ring, and automatic lanyard and sleeve disconnect. The release pin is attached to both lanyards and may be actuated by either. The operating forces required are manual 15 to 25 pounds and automatic 15 to 35 pounds. The supply of oxygen contained by the emergency bottle is sufficient to provide pressurization and breathing oxygen for the occupant for an ejection at the maximum altitude capability of the aircraft.

PERSONNEL SERVICES DISCONNECT (COMPOSITE DISCONNCT)

On most aircraft equipment with ejection systems, a composite disconnect is provided. The purpose of the disconnect is to provide a single point connection for quickly connecting and disconnecting the pilot's pressure suit or anti-g suit to the aircraft anti-g system, oxygen system, communications, and pressurization/ventilation air.

Scott Disconnect

The Scott composite disconnect is a small triangular shaped assembly comprising three blocks. The center or intermediate block is attached to the left-hand rear corner of the survival kit. The lower block is fastened to the aircraft and the upper block separates with the pilot upon leaving the aircraft. On separation from the seat after ejection, the upper block remains attached to the intermediate block, providing oxygen flow to the crewman.

The upper block contains the oxygen line, pressure suit hose, anti-g hose, and electrical leads to the pilot's or crewmember's mike and headset. A manual release handle (yellow pear) is provided for manual release of the upper block by the pilot or crewmember.

FULL PRESSURE SUIT

The full pressure suit currently in use is designated MK IV. The suit consists of five main components—the waffle weave under garment, torso unit, helmet, gloves, and boots.

The Mk IV full pressure suit is illustrated in figure 14-2, and is described in the following paragraphs.

The full pressure suit is a flexible pressure-tight garment for wear by flight personnel in aircraft with high-altitude capabilities. Its function is to protect personnel from the effects of low ambient pressures and of explosive decompression. It is also intended to protect the wearer from wind blast and exposure to extreme ambient water temperatures as a result of emergency ditching of an aircraft.

The suit torso is tailored to be a closely fitted coverall type garment encompassing all of the body except the head and hands. A neck ring is the attachment point of the helmet and also acts as a pivot for the head and neck. Incomporated in the helmet are the oxygen breathing regulator and communications system. The gloves extend from the lower one-third of the forearm to the fingertips. The helmet and gloves, when attached to the torso, form a complete assembly.

Impact-resistant flying boots are used with the Mk IV full pressure suit. The flying boot is impact and water resistant and is 8 inches high when fully laced. The boots are designed to allow lacing above the ankles, preventing their loss during bailout and offering support for the ankles upon parachute landing.

Suit accessory equipment consists of an integrated flotation garment with parachute harness and waffle weave underwear for use in cold climates. (See fig. 14-3.) An anti-g suit is worn when operational requirements warrant.

Under normal conditions, with the cockpit adequately pressurized, the pressure suit remains in an unpressurized state and any slight

SPIN 11143

PR.325

Figure 14-2.—Mk IV full pressure suit.

pressurization that occurs is due to high ventilation flows. The ventilation air is supplied from the aircraft air-conditioning system, monitored through the pilot's manual control valve, and channeled by way of a disconnect in "Trilok ducting" which is an integral part of the torso. This air flows through the ducting and exits at the wrist, ankles, crotch, and neck area. It then flows into the body of the suit so as to remove excess moisture and cool the body. The air leaves the suit exhaust port and is expelled through the relief port of the suit controller into the cockpit. In addition, to ventilation, this air also pressurizes the suit when required.

The full pressure suit system is designed to respond to, and function under, several distinct conditions that might be encountered in flight.

1. In normal flight with adequate cabin pressurization, the suit is provided with a flow of ventilation air to maintain the body at a comfortable temperature level.

2. When cabin absolute pressure falls below 3.5 psi (atmospheric pressure at 35,000 feet), the suit will immediately become pressurized by ventilation air.

3. If ventilation air is lost, the aircraft oxygen supply will pressurize the suit as well as supply the breathing oxygen.

4. During bailout, the emergency oxygen supply will pressurize the suit as well as supply breathing oxygen. The design of this oxygen breathing system is unique in that there is never any need for pressure breathing. While wearing the full pressure suit, one never has to resort to pressure breathing above a slight 0.1 inch of water pressure. The freedom afforded by this system of not having a mask tightly cinched across the face and covering the nose and mouth is a pleasant advantage. In addition to these advantages, the helmet visor offers a maximum windblast protection.

Pressure Suit Controller

The full pressure suit mounted contoller is installed on the full pressure suit torso at the exhaust port fitting. This system is necessary for functional compatibility with the pilot's universal upper block disconnect system. In addition, this system increases reliability and maintainability of the pressure control system.

The controller is an aneroid controlled exhaust valve which monitors the rate of flow of exhaust gases from the suit to obtain an absolute

11144

PR.326

Figure 14-3.—Full pressure suit accessories.

suit pressure of 6.9 ± 0.3 inches of mercury (equivalent to 35,500 ± 1,000 feet).

In normal flight with cabin pressure, ventilating air passes through the suit to the contoller and then escapes into the cabin. If cabin pressure fails above 35,500 feet and pressure is still available from the aircraft engine, the controller maintains suit pressure at the cortect absolute altitude of 35,500 feet. If pressure from the engine is also lost, aircraft oxygen will be automatically supplied by the controller to fill the suit to 3.5 psi.

TORSO HARNESS SUIT

The integrated torso harness suit is designed for use in Navy aircraft with integrated parachute restraint harness systems. (See fig. 14-4.)

Prior to acceptance of the integrated torso harness suit as a standard item of equipment, an extensive test program was completed to determine its suitability for service usage. As a result of these tests, the integrated parachute harness was adopted for use in ejection systems. The integrated system reduced overall bulk and weight, improved comfort, mobility, and retention, and provided better donning and doffing features.

The integrated torso harness suit consists of a sleeveless, legless, fabric garment within which is incorporated the parachute and restraining harness. The garment is closed by means of a slide fastener running the length of the front panel. The harness is secured for a snug fit by an adjustable chest strap located on the upper front of the suit. This feature consists of two harness straps exposed through reinforced outlets in the suit. Adjustments in the harness are taken up through these straps. After the desired adjustment is accomplished, the loose ends of the straps are engaged with the reversible friction adapter for security.

PR.327

Figure 14-4.—Torso harness suit.

The front panel contains an oxygen hose retainer channel to eliminate the possibility of the oxygen mask being carried away by wind blast during the high-speed bailout. The parachute risers and shoulder harness restraint straps attach to the connector links located on the right and left side of the upper chest. The aircraft lap belt attachments engage the two connectors which are located on the lower front panel at the junction of the upper thigh and lower abdomen.

The front panel also contains an attachment snap on the left shoulder strap for the attachment of the oxygen mask when not in use and a protective flap for the oxygen hose coupling at the junction of the hose.

The suit is designed so that by donning one garment and subsequently attaching it at four points the pilot is equipped with a parachute, shoulder harness, lap belt, and pararaft.

Sizing

Although the torso harness suit provides restraint during both normal operation and emergencies, proper sizing to the individual is mandatory to obtain maximum protection.

The individual should don the suit to determine that the fittings at the chest and at the main sling that crosses the buttocks are in proper positions. The chest fittings should ride in the fleshy portion of the chest and not be positioned too high near the collar bone. The main sling should be positioned well beneath the buttocks when the individual is in a seated position rather than behind the individual. Final determination of proper sizing should be made by the individual entering the aircraft cockpit and hooking up at the four attachment points. The hockup should be made without excessive slack in the restraining harness. It should be noted that utilization of the adjustment feature on the harness can be best made by assuming a squatting position and wriggling the body while adjusting both sides of the chest straps.

Donning

The integrated torso harness suit is worn as an outer garment over standard flight clothing such as summer flight suit, anti-g suit, and antiexposure suit. In view of the increased bulk of the antiexposure suit, when this garment is worn, it is necessary that the individual be fitted with a torso suit generally one size larger than normally used with other flight clothing. The integrated torso harness suit is furnished in 12 sizes.

ANTI-G EQUIPMENT

Anti-g equipment is currently installed in high performance aircraft to counteract the effects of prolonged acceleration on the pilot. The ill efects of such acceleration range from

11[illegible]

excessive fatigue and decreased alertness to blackout and unconsciousness.

Effects of Acceleration

Although there is no limit to the speed a human can endure in straight and level flight in an aircraft, changing speed or direction can lead to reactive forces of inertia to which the body has a sharply limited tolerance. In the case of extreme stresses exerted by acceleration of the type met in seat ejection, ditching, or parachute opening shock, the short duration of the acceleration restricts its effects. However, changing the direction of flight often produces prolonged radial acceleration (longer than a second) which can have dangerous effects.

At 5 g's the pilot's body is exposed to a force of inertia which increases its "weight" and that of its components five times. This increased "weight" has many effects. The pilot is pushed down into his seat. His arms and legs feel like lead and manipulation of the controls becomes more difficult. In addition, the extra weight of the viscera (internal organs) causes abdominal and chest discomfort. Most important, however, is the effect on the circulatory system.

At 5 g's the pressure exerted by the column of blood between the head and the heart becomes just about equal to the blood pressure in the arteries. As a result, the pressure supplied by the heart is not great enough to pump an adequate supply of blood to the head.

To counteract these effects, the pressure in the arteries must be increased above the heart level. At the same time, distended vessels and tissue and fluid spaces in the regions below the heart must be restored to normal. This is accomplished by the anti-g suit. With the anti-g system, compressed air is metered to the suit in proportion to the acceleration, and the suit compresses the legs and abdomen of the wearer by an amount proportional to the acceleration. Thus, the suit prevents venous pooling in the abdomen and lower extremities and forces blood from the lower to the upper part of the body. This effect increases venous return to the heart and increases resistance to the shifting of blood to the lower limbs. In addition, it causes the diaphragm to be raised and this decreases the distance between the heart and the eyes and/or the brain. Altogether, it increases the tolerance of the pilot an average of about 2 g's.

Without an anti-g suit, the average pilot can withstand 4.5 to 5.5 g's without losing vision or blacking out. With a suit, he is capable of withstanding 6.0 to 7.0 g's. However, this protection is available only for sustained accelerations of 4 to 5 seconds or longer in maneuvers other than snap maneuvers. Anti-g equipment does not offer protection in snap maneuvers where 10 to 12 g's can be applied in approximately 1 second. Such brief forces are not as harmful to the body as lesser forces which are sustained for a number of seconds.

Anti-G Suit (Mk 2A)

The Mk 2A anti-g suit is furnished in four sizes and has five interconnected bladders as shown in figure 14-5.

Anti-g suits are made of nylon. This material offers flash burn protection equal to treated cotton and in addition affords the strength characteristics necessary in this garment and not found in the cotton fibers available to date. However, since nylon does melt and forms droplets which retain heat and can cause burns, additional clothing should be worn

PR.328

Figure 14-5.—Anti-g suit. (A) Internal bladder arrangement; (B) Mk 2A cutaway type.

to protect against possible burns from this droplet formation.

Anti-g suits are fitted by the flight surgeon, often aided by a PR. The suit should fit snugly, especially at the waist. A snug fit means better protection and more comfort under g forces.

Experience and accident investigation have proven that burns resulting from the ignition of tight fitting material are far less severe than those resulting from loose fitting material. This is another reason why a correct fit is important.

If there is any doubt about the fit, the wearer should sit in the same position as in the aircraft and inflate the suit orally. The bladders should compress at the waist, calves, and thighs firmly and evenly.

ANTIEXPOSURE SUITS

Antiexposure suits are designed to be worn on cold weather flights by all personnel. They provide warmth and buoyancy in case of emergency bailout or crash landing at sea. They are effective on land and in the water, and without their protection from cold temperatures and near freezing water the individual would freeze to death quickly. A suit and liner have given protection from exposure for 2 hours in water at 28° F. In subzero weather on land, a suit will give protection for extended periods of time.

These suits offer a positive means of buoyancy because they are waterproof and retain air. Only when full of water will the suit reach zero buoyancy. For greater ease in swimming, one should get into an upright position and release the entrapped air by pulling the neck seal away from its seat.

Mk 5A Constant Wear

The Mk 5A coverall assembly consists of two garments—the outer shell and the insulation-ventilation liner. It offers protection from the elements and provides a means of admitting and distributing ventilating air during preflight and flight operations.

OUTER SHELL.—The outer shell is made of a nylon knit material having "stretch" qualities similar to that found in mens socks, T-shirts, etc. One side has been coated with a neoprene rubber compound for waterproofing. The suit is equipped with a long diagonal opening extending from the crotch upward over the front and slightly over the left shoulder. This opening is sealed with a waterproof slide fastener. This fastener is similar to a conventional fastener except that when closed, it forces together two overlapping rubber lips. To insure a NORMAL life and for ease in opening and closing the slide fastener, it should be kept lubricated with the appropriate silicone type compound.

A protective flap has been placed along the entire length of the slide fastener for protection against the parachute hardware, webbing straps, and other objects which might cause unnecessary damage to the slide fastener.

This flap is secured with short lengths of fastener tape. To close the flap, simply press the matching sections of tape together; to separate, and peel the tape halves apart.

Medium sized stretch socks are cemented to the legs of all suit sizes 36S through 40L and large size socks are attached to sizes 42R through 46L. Socks of both sizes are furnished in each repair kit for use when an individual requires a size other than the one attached.

The wrist seals are conically shaped and attached to the sleeve. Wrist seals are supplied in 3 sizes—small, medium, and large. Two sets of wrist seals are provided with each coverall as follows:

1. One set each of sizes small and medium with coveralls sizes 36S, 36R, 38S and 38R.
2. One set each of sizes medium and large for all of the remaining sizes.

Located at the lower pack portions of the legs is a pair of ventilation air exhaust valves which serve as the outlet for the ventilation air after it has circulated over the body. These valves were designed to exhaust air and yet function as watertight seals in the event that ditching in the water becomes necessary.

Normally, most of the ventilation air will exhaust from the open neck seal of the Mk 5A outer shell; but in the event the neck area is blocked or the neck slide fastener is closed during ventilation, the valves will serve as the sole outlet for the exhaust air.

The exposure suit neck seal is provided with Velcro fastener tape. It must be zippered up during carrier launch and recovery, takeoffs over water, and flying over water.

Two pairs of leg pockets or a total of four pockets are provided on each garment. In addition, there is also a cigaret-pencil pocket located on the left arm. Figure 14-6 shows the Mk 5A outer shell.

01148

PR.329

Figure 14-6.—Mk 5A outer shell.

INSULATION-VENTILATION LINER.—The insulation-ventilation liner (as the name implies) offers excellent insulation as well as ventilating properties. It is made with a lightweight, closely woven nylon outer covering and an inner layer of fire-retardant cotton fabric. Sandwiched between these two layers is a dacron fiberfill batting material. When kept dry these features offer the necessary insulation for the suit.

The ventilation distribution system is integrated within the liner between the outerface material and the dacron batting. It consists of a bladder or reservoir positioned across the full width of the back and a pair of arm and leg ducts. These ducts emanate from the bladder to each of its corners, then distribute the air to points near the sleeve and leg endings of the liner. The air then passes over the body for cooling and finally exits through the open neck seal and/or the exhaust valves of the Mk 5 outer shell.

EXTRA EQUIPMENT.—Available for use with each Mk 5 antiexposure suit are a ventilation hose, an ant-g hose, gloves, footwear, an inflatable hood, and cover plates.

The ventilation hose and the anti-g hose are fitted individually, and cut and assembled in accordance with Air Crew System Change No. 15.

The ventilation hose has a spring-loaded capped disconnect at one end and an elbow fitting at the other. The elbow engages with the air inlet port under the left sleeve, while the spring-loaded disconnect engages with a fitting leading from the air-blower source.

The anti-g hose terminates with a conventional anti-g male disconnect at one end and an elbow fitting which screws onto the fitting cemented to the Mk 5 outer shell.

NOTE: Red colored fittings are for ventilation purposes, and green colored fittings are for anti-g use.

The leather gloves are fully insulated and treated to resist water penetration through the leather surface. A rubber wristlet is bonded to the opening of the glove to prevent entry of water into the glove.

Insulated rubber or leather type boots are available in the supply department for use with the Mk 5A. The rubber boot is more cumbersome, but offers greater protection than the leather boot. However, additional warmth may be obtained with the leather boot by wearing heavier wool socks.

The inflatable hood is normally folded compactly and stowed in a coverall pocket for easy accessibility. After immersion in the water, the crash (protective) helmet should be removed and the hood donned, the snap fasteners engaged, and the hood orally inflated through the oral inflator valve on the left side of the hood.

11149

INSPECTION AND TESTING.—When the Mk 5A is not being worn, it should be hung inside out on a broad shouldered wooden hanger in a cool, well-ventilated area.

Periodically, inspect the suit, inside and out, for deterioration and physical damage such as separations at seams abrasions, tears, pinholes, cracking due to weather, and damaged slide fasteners.

At the end of each season, and at other times when it is suspected that the Mk 5A outer shell has a leak, the following procedures are used to locate the defective areas:

1. Close the entrance and neck slide fasteners.

2. Close the ventilation air and anti-g ports with the cover plates and turn the suit inside out.

3. Seal off one of the sleeve openings by the use of C clamps and 1 1/2-inch wide strips of 1/8-inch thick steel. The steel strips must have a strip of rubber sheet bonded to one side to avoid damaging the suit.

4. The neck area is sealed by clamping a pair of aluminum strips as shown in figure 14-7. The purpose of the aluminum strips is to prevent damage to the slide fastener.

5. Inflate the suit with air, through the sleeve that is not clamped, to a pressure of 6 inches of water. Air pressure in the suit may be observed by the use of a gage attached to the air inlet line.

PR.330

Figure 14-7.—Neck seal test jig.

6. Shut off the air supply and read the pressure after 5 minutes. If the pressure does not drop below 5 inches, the suit should be considered satisfactory. If the pressure drops below 5 inches, maintain the pressure in the suit and apply the soap and water test as follows: Apply a solution of mild soap and water to the suit with a soft bristle brush. With a white pencil, mark all leaks that are indicated by bubbles.

7. Release the air pressure from the suit and rinse it with clean water. Allow the suit to dry 24 hours before making repairs.

8. Prior to applying adhesive to any surface, clean the area to be repaired with a dry, clean cloth or brush. A solvent (toluol) may be used in small amounts where it is absolutely necessary.

9. Three coats of cement must be applied to a fabric surface, and two coats to a rubberized surface. Allow each coat to dry one-half hour before applying the next. NEVER SKIMP ON COATS OF CEMENT.

10. Allow 24 hours cure time for the adhesive and retest the suit in accordance with the procedure described in the foregoing paragraphs.

NOTE: Overage adhesive may appear gelled, but do not discard it before attempting to restore it to a usable condition. Add to the adhesive small amounts of solvent (50 percent ethyl acetate and 50 percent toluol) and stir. If the gelled adhesive dissolves and becomes a free-running fluid, place a drop on the index finger. After 1 to 2 minutes, press the thumb against this drop and hold for a few seconds. Release the pressure and slowly separate the thumb and index finger to 1/8 inch. If the adhesive appears tacky and forms webs, the adhesive is satisfactory for use.

CLEANING.—The liners for the Mk 5A are ordinarily dry cleaned. However, when dry cleanining is not feasible, the following laundering process may be used.

To a container of clean water having a temperature of 90° F, add any neutral synthetic detergent in the proportion of 1 teaspoon per gallon. Gently dip the garment into this solution several times to loosen any foreign matter. Squeeze (do not wring) out excess cleaning solution. Place the garment on a flat surface and rub gently with a cellulose sponge or soft bristle brush until clean.

Rinse in clean cold water.

Remove excess water (squeeze).

SPECTRUM ANALYSIS

The measurement of frequencies employed in radar operation falls into two general categories, transmitter frequency and receiver frequency.

For the transmitter operation of any given radar system, a range of frequencies is assigned for that system. Therefore, the transmitter must operate within this band of assigned frequencies if normal operation is to be expected. Transmitter operation is restricted to a certain range of frequencies for the following reasons:

1. The associated waveguide tuning adjustments cover only a limited range of frequencies.

2. Interference between radars used for different types of services could result if all radars were permitted to operate in the same band. For this reason, airborne S-band and shipboard S-band radars usually operate in different parts of the band.

Radar transmitters may be either fixed in frequency or tunable. If the frequency of a fixed-frequency transmitter is measured and found outside the operating band, the magnetron should be replaced. Tunable transmitters may be adjusted to any frequency within the operating band. This is a very desirable feature where several radars are in use in a limited area—each one may be tuned to a different frequency to prevent interference. In addition, when jamming is present, a different frequency may be free of the jamming signal. Since the operating bands are fairly wide, transmitter frequency tests do not require extreme accuracy.

1112

Suspend the liner on a hanger by the shoulders and allow to dry thoroughly in the air (do not spin or use heat in drying).

CAUTION: Do not iron or press this garment.

Mk 4 Constant Wear
Antiexposure Suit

The Mk 4 antiexposure suit consists of an outer suit of watertight material with attached boots and accessories, including gloves. The outer suit is constructed of a coated fabric which is permeable to moisture vapor, but impermeable to water. The suit has elastic wrist seals, neck seals, and rubber boots.

The insulating liner, which is worn under the outer suit, is a two-piece winter flying suit (jacket and trousers). It is provided primarily for its insulating qualities.

The type 4 boots have a sealed air chamber for cold protection. This chamber expands with increasing altitude and may be vented by the small valve located on the side of the boot. This will relieve the air from the boot and also relieve discomfort at high altitude. The boot is worn over a light or medium sock.

ACCESSORIES.—Accessories used with the Mk 4 suit are gloves and g-suit hose cover. The gloves are quick-donning, sealed, insulated mittens, left and right interchangeable. To prevent loss, they are carried in the glove pocket of the outer liner and are attached to the pocket by a lanyard.

Accessories not furnished with the suit are the detachable hood and five-fingered winter or summer gloves.

The Mk 4 constant wear antiexposure suit has been designed for use by flying personnel on all flights where unprotected or prolonged exposure to the conditions of cold air and cold water as a result of abandoning an aircraft would be hazardous or could prove fatal. To receive full benefits of its design, it is important that personnel wear these suits and accessory items of clothing exactly as prescribed.

Quick-Donning Antiexposure Coverall

The quick-donning antiexposure suit provides protection against exposure and is designed for donning immediately before landing at sea. The coverall is constructed of a light waterproof material with attached foot covering and elastic type wrist seals and neck seals. It consists of three separate components—the coverall, the hood, and the glove assembly. The coverall consists of a single-piece garment which envelops the body of the wearer, with the exception of the hands and face. The hands and face are given protection by the hood and mittens. These two items are stowed in the pockets of the coverall. The suit comes in one size and is stowed in a carrying case.

USE OF THE SUIT.—When it is necessary to abandon an aircraft while over water, the quick-donning exposure suit should be worn over the flying clothes, but under the lifevest and parachute harness.

The hood of the suit is made with a sufficient fullness so that it can be worn over the headgear. Use of the hood is optional, as the suit is watertight whether the hood is worn over the head or left folded under the neck closure.

The mittens are normally worn after boarding the liferaft. They will provide protection against the cold even though wet. Figure 14-8 shows the coverall, hood, gloves, and case.

WEARING INSTRUCTIONS.—The steps listed below outline the procedures for donning the suit:

1. Exercise caution when putting on the suit. Do not damage it by snagging, tearing, or puncturing.
2. Remove the suit from the container and unroll.
3. Grasp it by the hip section and put the feet into the boots. Then pull the suit on over the shoulders while extending each arm, in turn, through the sleeve openings.
4. Pull the neck seal over the head.
5. Adjust the neck properly. Do not allow the undergarments to protrude between the neck seal and neck as this will prevent a watertight, airtight seal.
6. Close the watertight slide fastener.
7. After closing the slide fastener, the entrapped air should be vented out through the neck opening.

When contacting the water, jump in feet first with the arms close to the sides of the body or held together over the head.

INSPECTION.—To prolong the life of the suit and maintain its reliability, a careful inspection of the coverall should be made when issued and at alternate calendar inspections thereafter.

1. Inspect for cracks, tears, holes, and seam separation; defective snap fasteners, buckles, slide fastener, webbings; and deterioration from foreign substances.

011151

191

PR.331

Figure 14-8.—Quick-donning antiexposure coverall, hood, gloves, and case.

2. Make all inspections on a smooth surface, free from harmful agents.

3. To insure long life and ease of operation of the slide fasteners, it is essential that the teeth of the fastener be cleaned free of talc, dirt, etc.

4. Defective suits are returned to the nearest depot-level maintenance activity.

11152

Antiexposure Suit (Wet Suit)

The ventilated wet suit is fabricated from a laminated cellular foam consisting of black polychloroprene cellular rubber 3/16 inch thick. The outer surface has a "grid" pattern and the inner surface is permanently bonded with knitted stretch nylon fabric.

A ventilated manifold assembly is cemented to the inner surface of the back of the suit, with spacers to permit the tubes to bridge the knees and elbows along the outer sides. To minimize body contact with the garment and to assure adequate internal ventilation, spacers are also provided at the back, seat, and rear thighs, chest, and arms.

The slide fasteners of the suit are stitched with polyester thread, and all seams are reinforced with a special tape and adhesive. Figure 14-9 shows the wet suit construction.

ACCESSORIES.—The accessories required to be worn with the suit in order to achieve 90-minute protection are special nonabsorbent two-piece 100 percent polyvinyl chloride fiber insulation underwear, exposure mittens, and an inflatable exposure hood.

The hood and mittens are stowed in the Nomex flight coverall which is worn over the suit assembly. The Nomex flight coverall also prevents the wet suit from being torn and protects the wearer from fire.

FITTING.—To assure precise fitting of the suit, eighteen sizes will be procured to fit airmen.

PR.332

Figure 14-9.—Wet suit construction.

LIFEVESTS AND PRESERVERS

Mk 2 Lifevest

The Mk 2 pneumatic lifevest was designed to be comfortable when worn in flight. To accomplish this, it is worn in its deflated state which permits the wearer all the freedom of movement necessary for the performance of his duty. When inflated, the vest must give adequate and properly distributed buoyancy. Fully inflated, the vest will provide a minimum buoyancy of 30 pounds.

Figure 14-10 shows the Mk 2 lifevest deflated.

An important feature of the vest's supporting qualities is that its back lobe (head support) maintains the wearer's head above the surface while the harness suspends him vertically in the water. Since the vest is self-righting, when properly worn and adjusted, it will float the wearer in the safest position with his head out of the water. As a further aid to rescue, small tabs and pockets are fashioned to the vest's front lobes for holding signaling equipment and shark repellant.

The body of the vest is fabricated from polychloroprene coated nylon fabric. The vest is made in three independent compartments. The

S41153

PR.333

Figure 14-10.—Mk 2 lifevest.

inside and outside compartments are inflated by carbon dioxide gas, and the middle compartment is inflated orally through an oral inflation valve and tube.

Deflation of the CO_2 compartments can be accomplished only by removing the CO_2 inflator caps. The air compartment is deflated by depressing the oral inflation valve. A nylon

611154

webbing harness, complete with adjusting and fastening devices, maintains the vest position on the wearer's body.

BUOYANCY.—When the two CO_2 compartments are inflated (from the standard 8-gram cylinders), the buoyant force (lift) of the vest is 20 pounds. If the center air compartment is also inflated (blown up by mouth), the buoyant force is increased to 30 pounds. This means, in effect, the weight of a person in the water is less than his weight in air by an amount equal to 30 pounds plus the buoyant force of the water.

Since the body, in water, weights a negligible amount in comparison to its weight in the air, 20 or 30 pounds buoyance is all that is needed to float the body successfully. It is interesting to note that inflation of the air compartment alone will also produce a 30-pound buoyant effect. A vest inflated to a pressure of 1 1/2 psi is capable of floating a 30-pound steel weight in fresh water.

FITTING.—All lifevests should be individually fitted to allow enough slack in the harness so it will not bind the wearer after inflation. The simple fitting procedure is as follows:

1. Have the wearer put on the vest and secure the harness link fastener, the fasteners which join the lobes, and the fasteners which hold the lobes to the waist belt.
2. Inflate the vest by mouth to its maximum volume.
3. Adjust the harness adapters to obtain a comfortable, snug fit.
4. Remove the vest and deflate by depressing the oral inflator valve.

Unscrew the valve lock, and the vest is ready for emergency inflation.

PREFLIGHT INSPECTION.—Every wearer must be able to determine the condition of his lifevest. The following inspection should be conducted by the individual prior to every flight:

1. Inspect all exposed metal parts for evidence of corrosion.
2. Inspect the inflation assemblies and safety wire.
3. Check the carbon dioxide cartridge to insure that the cartridge does not have a punctured seal.
4. Inspect the cloth seams and harness for evidence of wear, snags, tears, and abrasions.
5. Inspect all the emergency equipment for operation, security, and missing items.

CALENDAR INSPECTION.—The calendar inspection consists of the following tests: Preparation, updating configuration, functional test, inflation assembly inspection, leakage test, checking the physical condition and quantity of survival items.

The functional test will be performed upon issue and every fourth inspection cycle thereafter. The leakage test and all other inspections will be performed upon issue and every inspection cycle thereafter.

The above tests can be found in NavAir 13-1-6.1.

Mk 3C Life Preserver

The Mk 3C is a self-righting life preserver offering a minimum of 60 pounds buoyancy and capable of supporting a survivor vertically in the water. It consists of two independent flotation cells. These cells are made of chloroprene coated nylon cloth and joined together by gussets. (See fig. 14-11.)

Each cell is equipped with its own oral and mechanical inflation system. They are inflated orally by turning the knurled sleeve down, pressing in on the mouthpiece and blowing into the inflation tube. Releasing the pressure on the mouthpiece closes the self-closing valve. Upon completion of the inflation, the knurled sleeve should be turned up against the mouthpiece to lock the valve in the closed position.

The mechanical inflation assembly consists of an inflation valve, a check valve, and a 29-gram CO_2 cylinder. A lanyard with a toggle is placed within easy reach of the wearer.

The deflated life preserver is contained in a carrying case of heavy nylon fabric. This case has pockets attached for two Mk 13 Mod 0 distress signals and a means of attaching one dye marker and one shark repellent.

FITTINGS.—Fitting the Mk 3C is a comparatively simple procedure. With the markings "right" and "left" on the outside, don the preserver as a belt and join the two snaps in the front. This will secure the case snugly and comfortably around the waist. An adjustment band is provided on the back of the carrying case to facilitate individual adjustment.

INSPECTION.—The sequence of inspection tasks is to be performed is similar to the sequence for the Mk 2 life preserver and can be found in NavAir 13-1-6.1.

MAINTENANCE.—Before attempting to repack a Mk 3C life preserver, make sure that all checks and tests have been properly made and that the cells are completely deflated. Lay

11155

PR.334

Figure 14-11.—Mk 3C life preserver.

the empty carrying case on a flat surface with the labeled right side on your right side as you face the case. Insert the cells through the retaining webbing loops.

Fold the rear section of the cells forward to approximately the same width as the adjustment envelope of the carrying case. Lay the folded section of the cells in the adjustment envelope and fold the flaps of the envelope over the cells.

Hold the adjustment envelope closed and fold forward. Fold the flaps over the adjustment envelope and engage one span on each side of the center of the envelope.

Attach dye marker and shark repellent, insert the distress signals.

Insert CO_2 cylinder through retainer loop and screw into inflator assembly, making sure that antichafe protector is in place.

Tuck in cells and stow oral inflation tube. CAUTION: Stow inflation tube without any sharp bends.

Insert a cord through the securing loop and pull the securing loop through the eyelets of each flap. Complete passing of securing loop through flap eyelets, insert nylon pin, and remove cord.

The completely packed Mk 3C life preserver is shown in figure 14-11.

1115611

- Mk 4 Life Preserver

The Mk 4 life preserver (fig. 14-12) was designed expressly for use with the Mk 4 full pressure suit. Although the materials used in manufacturing (as well as the design configuration) differ, the function of the Mk 4 is the same as the Mk2 and the Mk 3C.

PR.335

Figure 14-12.—Mk 4 life preserver.

1115711

The Mk 4 should be inflated periodically in accordance with current directives and checked for leaks. Remove as much air as possible after these tests to prevent unnecessary inflation at altitude from expansion of the residual trapped air in the infiltration compartments. Routine care and maintenance is the same as for other life preservers.

LPA-1 Life Preserver

The LPA-1 life preserver, shown in figure 14-13, is a new preserver which has been developed by the Aerospace Crew Equipment Department. This life preserver has a buoyancy of 65 pounds and has been found capable of use with every existing item and configuration of survival equipment of naval aviators, including the full pressure suit, nonintegrated harness and MA-2 torso harness. It may also be worn without a harness. The LPA-1 preserver will permit servicewide standardization to a single common-design life preserver for aircrewmen in lieu of the three different types in current use.

DESCRIPTION.—The preserver has a cover made of coated nylon duck which features Velcro fastener strips that permit waist-size adjustment. The cover also has an adjustable belt that anchors the buoyant thrust of the waist lobes of the preserver when the preserver is attached to the flight suit in nonintegrated parachute harness configuration or in the no-harness configuration. When used with the integrated parachute harness, the waist section of the preserver is anchored to the torso suit in the same manner as the Mk 3C preserver.

Two Mk 13 Mod 0 signal flares can be installed in a small pouch beneath the right inflation lobe cover, and two dye markers can be attached to the left inflation lobe cover.

The preserver is constructed of coated fabric and, as mentioned earlier, provides 65 pounds of buoyancy when inflated with the two 28-gram capacity CO_2 cylinders. There are also two flexible oral inflation tubes which may be used if necessary. The collar section is inflated by one CO_2 cylinder and the front buoyancy lobes are inflated by the other CO_2 cylinder. This life preserver has the capability of inflation prior to water entry.

NOTE: The LPA-1 is not designed for release and expansion by oral inflation. When it is desired to inflate the entire cell through the oral valve, it is necessary to release the body lobes by removing both cotter pins from the retaining loops and to manually separate the hook and pile tape that secures the collar lobe.

CALENDAR INSPECTION.—The LPA-1 life preserver must be inspected in accordance with the instructions for the Mk 3C life preserver detailed in NavAir 13-1-6.1.

LPP-1 Life Preserver

The LPP-1 life preserver, shown in figure 14-14 weighs 3 pounds and provides a minimum of 34 pounds of buoyancy. The LPP-1 life preserver assembly consists of a single comparement, yoke type flotation garment, a pouch and belt assembly, an inflation assembly and a storage container. The preserver is designed to support the wearer's head above the water while the body rests at an optimum 45 degree angle. In the dry wear state, the belt, which is attached to the flotation chamber through the pouch, is secured about the waist.

The LPP-1 life preserver is designed and authorized for use by civilian or service dress-attired passengers flying in cargo or transport aircraft. The LPP-1 is also authorized for use by Navy and Marine helicopter aircrewmen using the T-65 Body Armor. For this latter application, the LPP-1 must be modified in accordance with NavAir 13-1-6.1.

COMPONENT DESCRIPTION.—The LPP-1 assembly consists of the following components:

1. Inflatable buoyance chamber: The inflatable buoyancy chamber, the basic component of the LPP-1, is constructed of chloroprene-coated nylon cloth. It is an airtight bag equipped with an oral inflation assembly and a manifold for attachment of a mechanical CO_2 inflation assembly. The inflatable chamber is further equipped with loops, flaps, pockets, and patches for attachment of all its complementary devices.

2. The adjustable belt assembly: The adjustable belt assembly consists of a 53-inch webbing belt, an adjustable buckle and clasp, a toggle assembly, and a toggle assembly pocket. The belt adjusts from a waist size of 30 inches to 52 inches. A wooden toggle is attached to the belt by a 36-inch length of type 3 nylon cord. During emergency use, the toggle and line are used to secure survivors together while in the water. When not in use, the line is wrapped

111581

around the toggle and the assembly is stowed in the toggle pocket located on the belt.

3. Pouch: A rubber-coated nylon cloth pouch contains the buoyancy chamber and other accessory devices. The pouch has two slots on the back panel for exit of the belt.

4. Storage container: An orange colored storage container is provided with each assembly.

PR.337

Figure 14-14.—LPP-1 life preserver.

11160

The transmitter frequency is readily measured by using the resonant cavity wavemeter section of the TS-757/UPM-32. The resonant cavity functions as an absorption type wavemeter. When tuned to the frequency of the transmitter, the cavity absorbs some of the microwave power. This reduction of power is indicated as a dip on the power monitor (meter) or synchroscope.

A convenient method of coupling the radar transmitter to the frequency meter is by use of the test set's special coaxial cable. One end is connected to the radar directional coupler, while the other is connected to the frequency meter input.

This wavemeter has a direct-reading dial for frequency indication. When the cavity is tuned to resonance, the frequency is indicated in megacycles per second in the FREQUENCY window. An attenuator is also included to prevent driving the power meter off-scale. While tuning the frequency meter, the control should be moved slowly. Otherwise it is possible to pass the resonance frequency without knowing it. The reason for this is that the power is detected by a thermistor which takes a short time to heat and react to the power applied to it.

The resonant frequency of the radar may also be indicated on the synchroscope. The reduction in power caused by absorption in the resonant cavity is apparent by a decrease in pulse amplitude on the CRT. This dip is usually easier to detect than the power meter. Final tuning, however, should always be done by the meter indication. Transmitter frequency may also be measured during spectrum observation.

Spectrum observation is the display of the magnetron's output on a synchroscope. By this method the technician may readily determine visually whether or not the magnetron is operating properly. Figure 16-25 shows an ideal spectrum of a pulsed magnetron. Note that the side lobes are very low compared to the main lobe, and that the main lobe falls off to zero on either side of the carrier frequency.

Figure 16-26 shows several examples of transmitter spectral displays that are less than ideal. In general, the distortion resulting from frequency modulation (fig. 16-26 (A) and (B)) is far more undesirable than distortion resulting from amplitude modulation (fig. 16-26 (C)). Both frequency and amplitude modulation may be present in a spectral display (fig. 16-26 (D)).

TRANSMITTER TROUBLES

The major troubles or indications of trouble met with in radar transmitters are incorrect operating frequency, poor spectrum, and low output. As a further complication, the troubles may occur intermittently.

Figure 16-25. —Ideal spectrum of a pulsed magnetron.

4113

Instructions for donning, wearing, and operation of the LPP-1 are pictorially presented on this container. The assembly is also shipped and stored within this protective, instructive container.

5. Emergency signal light: A water activated light is secured to the right side of the buoyancy chamber. The light, which has an operation life of 8 continuous hours, consists of a lens, connector wire, and battery, and offers a small, compact illuminant for the survivor. The lens is attached near the top of the preserver to provide maximum visibility while the battery hangs below to insure its contact with water.

6. Whistle: A whistle is provided and attached to the pocket by a length of cord. The whistle is stowed in the pocket located at the front center of the preserver.

7. Sea dye marker: One packet of fluoresceine dye is stowed within the pouch and is attached to the belt by a 12- to 15-inch length of type I nylon cord.

8. Shark repellent: One packet of shark repellent compound is stowed within the pouch and is attached to the belt by a 12- to 15-inch length of type I nylon cord.

OPERATION OF THE LPP-1.—The LPP-1 is manually inflated by pulling the inflation assembly lanyard down. In an emergency situation, the oral inflation valve should be used to top off an inflated preserver, maintain inflation of a leaky preserver or to inflate a preserver when the inflation assembly malfunctions or fails. The oral inflation valve is also used to inflate a preserver with air during an inspection test or to deflate a preserver in preparation for packing.

NOTE: The pouch must be opened and the flotation assembly unrolled prior to inflation through the oral inflation valve or inflation assembly. This does not apply for LPP-1's modified for use by combatant helicopter aircrewmen.

DONNING: Donning of the LPP-1 life preserver is accomplished as listed in the following sequence of steps:

1. Remove preserver from storage container.
2. Place belt around the waist with pouch in back. Toggle pocket should be on the left side.
3. Connect the clasp and buckle and adjust the belt to size on the right side.
4. Secure the excess belt with mating hook and pile fastener tapes.
5. Rotate pouch to front and readjust the belt.
6. When ready for use, unsnap the pouch and unroll the deflated buoyancy chamber up. Place head through opening and allow upper portion of chamber to rest on shoulders.
7. Remove the pouch containing the dye marker and the shark repellent from the bottom of the buoyancy chamber.
8. After egression from the stricken aircraft inflate the buoyancy chamber by pulling down on the inflator toggle.
9. Emergency use of the survival detection aids shall be as required. Emergency use of the signal light can be initiated by pulling the tab downward to open battery port, allowing sea water to activate the battery.

TEST, INSPECTION, AND MAINTENANCE.—Test, inspection and maintenance of the LPP-1 must be conducted in accordance with Aviation-Crew Systems Manual Navair 13-1-6.1.

PACKING THE LPP-1.—To pack the LPP-1 life preserver for noncombatant personnel, proceed as follows:

1. Insure that the preserver, pouch, belt and storage container have been inspected for any defects. Inspect the complete assembly for updating and compliance with latest modification listed in Navair 13-1-6.1.
2. Insure that survival items have been inspected for expiration and damage.
3. Insure that the belt is inserted through retaining patch on rear of preserver.
4. Lay preserver on a clean surface with inflation assembly facing up.
5. Insert ends of belt through slots in pouch.
6. Insure that each survival item is properly stowed or attached.
7. Position dye marker and shark repellent in bottom of pouch. Lock oral inflation valve.
8. Fold flotation tube sides over the width of pouch.
9. Roll flotation tube into pouch and close pouch.
10. Insert packed preserver into storage container.

To pack the LPP-1 life preserver for combatant personnel, proceed as follows:

1. Insure that the preserver, pouch, belt and storage container have been inspected.
2. Insure that the belt is inserted through retaining patch on rear of preserver. Close inflation assembly protective cover.

11161
0a.11

3. Tuck protective cover back panel through preserver neck opening.

4. Insert oral inflation valve through oral tube patch. Insert oral inflation valve loop through loop reinforcing patch. Stow oral inflation valve in loop. Insure that the oral inflation valve is locked.

5. Mate hook and pile tapes.

C3 11162

CHAPTER 15

STANDARD LIFERAFTS AND EQUIPMENT

Naval aircraft making operational flights over water are required to carry rafts which will accommodate all the assigned crew plus passengers. These rafts are manufactured in various sizes and configurations to meet the demands of all types of aircraft.

Pneumatic rafts are compact assemblies, capable of being stowed in a small area. They should be stowed so as to be readily accessible, preferably near an emergency exit. Never stow a raft under other equipment or cargo or near batteries. Protect them from heaters, engines, auxiliary power units, electronic tubes, and other sources of heat.

If the aircraft flight manual designates a storage place for rafts, this space should be used, unless otherwise directed by competent authority. Whenever possible, rafts should be stowed in the same place in all aircraft of the same model. This will enable the crewmen to become familiar with their location and thus avoid confusion in the event of a ditching. Rafts are made of rubber impregnated nylon fabric and are therefore susceptible to damage from maltreatment. However, they are surprisingly strong and durable, and have tenacious stability when afloat at sea.

It is the responsibility of the PR to inspect, pack, and maintain all of the various types of rafts and related equipment.

MULTIPLACE RAFTS

All multiplace rafts are of the same construction, but vary in size and in the quantity of equipment they carry. As a safety measure they have separate air compartments. This enables the raft to maintain its buoyancy, even in the event of a puncture of one of its compartments. In the Mk 4, for example, there are three air compartments—two automatically inflated by CO_2 and a seat compartment which can be inflated with a hand pump. The two automatically inflated compartments are separated by a vertical bulkhead amidships.

Each raft is enclosed in a carrying case secured with snap fasteners or a ripcord arrangement. As the raft inflates, the case is forced apart, and the inflated raft emerges from the case. The case may be used as an additional drogue, or sea anchor.

CONSTRUCTION

The body of the raft consists of an encircling buoyant tube and a fabric bottom. All rafts are manufactured in sections to provide the specified shape. The fabric bottom of the raft is applied without tension across the enclosure formed by the flotation tube and is attached securely to the underside.

Seams

All seams and attachments are secured by self-curing rubber cement. No stitches are used in the seams or through the fabric of any compartment. However, sewing is permitted in the construction of patches, oarlocks, disks, flap seats, cylinder carriers, lifeline supports, handles, and pockets.

The minimum overlap for seams is three-fourths of an inch (+1/4-0 inch). They are reinforced both on the inside and on the outside with type R tape (1 1/4 inch wide). The tape is applied in such a way that an equal amount of width is on each side of the seam edge which it covers. The cement is applied in a straight line, parallel to the edges of the tape, and extends approximately one-eight inch beyond the tape edges.

Bulkheads

The flotation tube is separated into two compartments by internal vertical bulkheads.

11163

Bulkheads are constructed of type N rubberized fabric and are either hemispherical or conical in design. The bulkheads are installed amidships, equidistant from the bow and stern, in such a way that the volume of the two compartments is equal. The bulkhead-to-tube attachment is reinforced on one side with type R tape, and on the other side with a hinge of wider type N tape. A 4-inch-diameter patch of type O fabric is installed on the bulkhead for protection against abrasion by the manifold diffusers when the raft is packed in the carrying case.

On some Mk 20 rafts the internal bulkheads are positioned on each side of the boarding stations. This provides a section which is deflated and offers ease in boarding the raft.

Inflatable Seats

An inflatable seat is installed in certain multiplace rafts, for example, the Mk 4, Mk 7 and Mk 12A-1. These seats are circular in shape and are constructed of type O fabric. The ends of the seat are tailored to fit the curvature of the flotation tube. Each end of the seat is blocked with type N fabric, making the seat an independent air chamber before it is installed. These seats are independently inflated by a valve, using the hand pump provided.

The seat is attached to the bottom of the raft with a hinge tape of type N fabric, extending the length of the seat tube. This method of attachment allows for expansion, and prevents undue stresses between the bottom of the raft and the seat.

Oarlocks

Some liferafts are outfitted with oarlocks. The oarlock consists of seven plies of type O fabric cemented together. A No. 11 brass grommet is set in each oarlock, located so that the bottom edge of the hole is 1 inch above the flotation tube. Each oarlock is attached to the flotation tube outside the top centerline in such a position that the upright portion, containing the grommet, is at an angle from the vertical, inclined away from the centerline. An oarlock is also attached to the top of the flotation tube at the stern so that an oar can be inserted through the oarlock and be used as a rudder.

Mast Holder

One mast holder consisting of an upper and lower structure is constructed in each raft. The upper part of the mast holder consists of an oarlock attached in a horizontal position approximately 3 inches above the inside centerline of the flotation tube. The lower part consists of a socket made of two plies of type O fabric and is 4 inches in length. The socket is cemented to a 4-inch diameter patch consisting of two plies of type O fabric. The patch is then cemented to the raft bottom directly in line with the hole contained in the upper part. Together, these mast holder parts can support an oar handle in the vertical position. The handle passing through the upper hole in the oarlock terminates in the socket.

The Mk 20 liferaft has two mast sockets. They are cemented to the center of the raft floor on opposite sides, back to back.

Supply Pocket

Each Mk 4 and Mk 7 raft has a supply pocket which measures approximately 8 x 8 x 2 inches. It is attached to the tube surface inside the raft by stitching the pocket to a patch and cementing the patch to the tube. Each pocket should be clearly and indelibly marked SUPPLY POCKET in 1/2-inch letters.

Supply Pocket and Bailer

Another type of supply pocket is attached to each multiplace raft except the Mk 20. This pocket measures 10 x 10 x 2 inches and is constructed from type O fabric. The pocket is closed by means of a slide fastener across the top, which is sealed with tape after the equipment is packed. A loop of semihard spring wire is contained in the seam around the slide fastener so the pocket may be fashioned into a bailing container.

The pocket is secured to the flotation tube by means of two large curtain type fasteners so that it may be detached. To avoid loss of the pocket, it is secured to the nearest lifeline patch with a 5-foot length of type III suspension nylon line. The words SUPPLIES AND BAILER are stenciled in 1/2-inch letters on the pocket. Below this, stenciled in 1/4-inch letters, are the words:

KNIFE, SIGNALING MIRROR,
WHISTLE, LINE, COMPASS
and MAST CLAMP.

11164

Cylinder Carrier

One cylinder carrier, suitable for holding the CO_2 cylinder securely in position, is provided with each raft. The carriers are constructed and located in accordance with applicable standard drawings for each particular raft.

Lifeline

A 1/4-inch nylon or orlon lifeline encircles the perimeter of the raft. The line is attached to the raft by means of lifeline loops or supports. The lifeline is secured to the supports with overhand knots to prevent the line from running free through the supports. A 4-inch slack in the line is allowed between the supports.

The supports are constructed of type III nylon tape, 1 inch wide. A strip of webbing 5 inches long is threaded through a slot in a 3-inch-diameter type O fabric disk, forming a loop 1 inch long. The loose ends are securely stitched to the disk and two rows of stitching are made through the base of the webbing loop. This assembly is then cemented to the top outside quarter of the flotation tube midway between the horizontal and vertical centerlines of the tube. A type O fabric disk, 5 1/2-inches in diameter, with a slot in the center, is then cemented over the loop assembly to the flotation tube. Each completed lifeline patch can withstand a 200-pound pull exerted in a direction perpendicular to the base of the patch.

Righting Handles

Each raft has righting handles. Each handle is constructed of a 11-inch length of type III, 1-inch nylon tape. The handle is covered by an outer patch of type O fabric extending beyond the edge of the disk and securely cemented to the raft. A 1-inch slack is allowed in the attachment to make them easier to grasp.

Boarding Handles

Each raft has boarding handles. These boarding handles are constructed in the same manner as the righting handles. They are attached to the raft in accordance with the applicable drawings.

Topping-Off Valves

A topping-off valve is installed in each flotation tube compartment of the raft. The topping-off valve is used for hand inflation purposes in conjunction with the hand pump. It also serves as a means for relieving high internal tube pressures that may possibly build up during hot, sunny days. Both valves are installed on the same side of the raft, on the top inside quarter midway between the vertical and horizontal centerline 4 inches from the vertical (internal) bulkhead.

Stenciled instructions relative to topping-off and deflation of the raft are applied on the raft flotation tube adjacent to the topping-off valves. Appearing in 1/4-inch black letters, the instructions are stenciled on a white rubber patch as follows:

TO INFLATE COMPARTMENTS MANUALLY: Attach hand pump to valve cap, unscrew cap 1 1/2 turns to the right and then pump to inflate. When desired pressure is attained, retighten valve cap and remove pump.

TO DECREASE PRESSURE: Open valve 1 1/2 turns to the right and bleed.

Inflation System

The valve of the CO_2 cylinder is threaded into the coupling nut of the manifold. Since multiplace rafts are constructed with internal bulkheads, the purpose of the manifold is to provide a common means of directing and diffusing the flow of gas from the actuated cylinder to each of the separate compartments at the same time. To do this the manifold outlets must bridge the internal bulkhead over which they are mounted. Figure 15-1 illustrates the operation of a raft inflation system.

All the exposed metal surfaces of the inflation system which might chafe the raft fabric while in a packed condition should be suitably and securely covered with cheesecloth or suitable scrap cloth.

MK 4 RAFT

The Mk 4 raft is designed to accommodate four men plus sufficient emergency and accessory equipment to keep them alive for 1 week at sea. It is 9 feet 2 inches long and 5 feet wide. Complete with all equipment and the CO_2 inflation system, its weight is 86 pounds. The CO_2 cylinder has an internal volume of 147 cubic inches and the raft is inflated to a pressure of 1 psi by a CO_2 charge of 3.25 pounds. This

11165 L

PR.338

Figure 15-1.—Multiplace raft inflation system.

pressure gives it a buoyant capacity of 1,800 pounds.

EQUIPMENT

The equipment carried in the Mk 4 raft differs from that carried in other rafts basically in the quantity carried, with a few minor exceptions. Therefore, all emergency and accessory equipment is covered here. Quantities for each individual raft are listed in table 15-1 of this chapter and NavAir 13-1-6.1.

Oars

Three complete oars and one additional section are supplied with each raft. These oars have a threefold purpose. They may be used for rowing or paddling, as reflecting blades for identification purposes in night rescue, and in varying combinations of length as a mast for rigging a shelter or in mounting a radar reflector.

The oars for the MK 4 rafts are approximately 5 feet long; whereas the oars for larger size rafts are approximately 6 feet long. The pneumatic raft sectional oar is shown in figure 15-2. The oars are constructed from aluminum alloy, and the paddle blade is coated with a retro-reflective material for night reflective purposes. Oars are stored in the accessories container of the respective rafts.

Hand Inflation Pump

Pumps are provided with all multiplace rafts and are used to inflate the rafts in case of failure of the CO_2 inflation system. The pump is also used to top off the raft after initial inflation with CO_2.

Hand pumps are stowed in the accessories container and held secure by a 3-foot length of type I nylon line.

Whistle

A whistle (police type) is provided for all rafts and is stowed in the supply pocket. The whistle is to be used by personnel for attracting attention of a rescue ship or personnel in foggy weather or at night. In still air and perfect silence, the whistle may be heard for 1,000 yards. Many successful rescues have been due to the use of a whistle. For security of the whistle, it is attached to a 3-foot line.

Gnd/Air Emergency Code card	1	1	2	1

Nylon Cord

For utility purposes, type I nylon line is supplied with each raft. It is supplied in lengths of 50 feet for use as prescribed in applicable directives.

Bailing Sponge

Bailing sponges are provided for all rafts. The bailing sponge is of the common cellulose variety and is provided in varying quantities for the different size rafts. The sponge is used for bailing water collected in the bottom of the raft, and may also be used for collecting rainwater for drinking purposes.

Raft Carrying Case

Rafts are packed in carrying cases constructed of orange-yellow-coated fabric corresponding to the color of the rafts. The carrying case is designed to hold the raft in a deflated but ready condition for inflation wherever it is stowed. The closing hems of the case are fitted with snap fasteners, capable of being released in any direction of pull. The tenacity with which these snaps hold the raft in its case must not be too great. The pressures exerted by an inflating raft must be sufficient to "pop open" the snaps and release the raft without damage.

Retaining Line

The purpose of the retaining line is to secure the life raft to a user, thus preventing its loss before and after the raft is inflated. The retaining line is constructed of nylon cord, type III, or nylon webbing, type II, orange-yellow in color. The line varies in length, depending upon raft application. One end of the line attaches

00144167

to the raft CO_2 cylinder while the other end terminates in a snaphook for attachment to the aircrewman.

Liferafts to be placed in wing or fuselage compartments of aircraft for remote control operation must be folded and packed WITHOUT carrying cases in accordance with the aircraft Maintenance Instructions Manual.

Righting Lines

In the event of capsizing, a righting line is installed on all Mk 4, Mk 7, and AR-4 multiplace rafts. This line is an independent piece of 1/4-inch nylon rope, 10 feet long, and is attached to the lifeline on the opposite side of the CO_2 cylinder at the center of the raft between the lifeline patches, by means of 2 half hitches.

Sea Anchor

The sea anchor furnished is a circular cone-shaped fabric device with an open bottom. The sea anchor is packed so that it falls into the water as soon as the raft is inflated. This reduces the danger of capsizing the raft by checking the drift and holding it "bow on" into a heavy sea. By reducing wind drift and slowing the raft down, the sea anchor also makes it easier for a man in the water to catch the raft. The sea anchor is also important in case of a helicopter pickup, for it helps keep the raft from drifting in the downdraft created by the helicopter rotors.

By virtue of the nature of its use, a sea anchor must be securely rigged to a strong mooring purchase. Such a mooring purchase is devised in a patch which, when cemented to the raft, is capable of withstanding a perpendicular pull of 400 pounds. Once the raft is inflated, a strong keeper line, which is longer than the one originally attached, should be secured between the raft and the sea anchor. In making the additional purchase, it should not be secured to the same mooring patch.

Hammock Bed

The raft hammock is suspended between the flotation tubes. The taut canvas provides a means of keeping off the floor when weather and sea conditions are adverse. The hammock may also be used to protect survivors from wind and rain.

The hammock is constructed of water repellent fabric, and is secured to the raft by wooden toggles and loops of webbing. One hammock is furnished with the Mk 4. Larger rafts are furnished with two. Hammocks are stowed in the accessory container.

Mast Clamp

The mast clamp is used primarily as an aid in rigging a sail. In lieu of the mast clamp, nylon cord can be used in securing a cross-member of an oar, serving as a mast. The clamp and line can also be used in securing a distress signal to an oar. The mast clamp is stowed in the raft supply pocket.

Emergency Equipment Container

The emergency equipment container supplied for the Mk 4 and Mk 7 rafts is drumlike in shape. The container has a slide fastener closure installed in one end for admittance of the equipment.

Each container is stenciled in 1-inch letters with the Mk number corresponding to the Mk number of the raft. A strip of type R tape accompanies each container. It is used for sealing the slide fastener after the container has been equipped. For shipment by the manufacturer, the empty container is secured to the raft by fastening the snap of the container line to the lifeline of the raft near the CO_2 cylinder.

Accessory Container

The accessory container is constructed of type O fabric. The oars and hand pump are among the items included and stowed in the accessory container. The container is protected at each end by a wad of felt or cheesecloth approximately three-fourths inch thick. This padding protects the equipment from damage when dropping the raft from aircraft. The hammock beds and paulin can be utilized to protect the other items stowed in the container. The following words are stenciled in 1/2-inch letters on the body of the container:

OARS, PUALIN, PUMP, HAMMOCK BED, SMOKE SIGNALS, DYE MARKERS, SPONGES.

Since multiplace rafts vary in size, the container sizes also vary to accommodate more equipment needed for the larger rafts.

11163

Signaling Mirror

The emergency signalling mirror is approximately 3 x 5 inches and consists of an aluminized reflecting mirror glass, a back cover glass, and a sighting device. It is used by personnel in rafts or on land to attract attention of passing aircraft or ships by reflection either in sunlight or in hazy weather. The reflections of this shatterproof mirror can be seen at a distance 3 to 5 times as great as those which a raft can be sighted at sea. On a clear sunny day, the mirror will reflect the equivalent of 8 million candlepower. Flashes from the mirror have been seen from a distance of 40 miles.

Figure 15-3 illustrates the operation of the signaling mirror. Past experience indicates that personnel may have difficulty using the mirror in a bobbing raft at sea. Practice signaling with the mirror on the ground should be encouraged as part of the training program for flight crews. Such practice will reduce the difficulty in case of emergencies. Before using the mirror, the protective coating must be removed from its surface.

PR.340

Figure 15-3.—Operation of the signaling mirror.

Jackknife

The jackknife is a scout type, consisting of one large blade, a combination screwdriver and bottle opener, and one can opener. It is furnished with a 3-foot lanyard. One jackknife is furnished with each raft and stowed in the supply pocket. The value of a jacknife, especially under emergency circumstances, need not be emphasized as everyone can visualize its usefulness. When in a raft, one should never let the opened knife dangle from its lanyard or lie on the bottom of the raft.

Pocket Compass

The magnetic card type compass is encased in a cylindrical transparent plastic cover with a reference line inscribed on the top of the case. A circular card swings on a jeweled bearing, while a centered pivot supports and suspends the card in its free movement.

To cage the compass and protect the jeweled bearing, it is stored in an inverted position. The compass is reasonably shockproof, but it should be handled with care if one is to expect reliable readings. Damage to the case will impair its waterproof qualities, and promote corrosion in spite of its internal corrosion-resistant construction. Fittings outside of the base adapt the compass for wrist wear. One compass is provided for each raft and is stowed in the supply pocket.

Water Storage Bags

The water storage bags are made of strong transparent pliable plastic and will hold 5 quarts of water. The open end is reinforced and is designed to hold itself in a closed position. To seal the bag, use must be made of the strap and buckle located near its end. The bag can be sealed tightly by rolling or folding its opening for a short distance, and by securing the folds with the strap and buckle.

11169

When the bag is not being used for holding water, it can be used for stowage of items in need of protection from salt water. Protecting articles in this manner can lead to contamination; therefore, articles should be wrapped in something to prevent lubricants and other contaminants from coming in direct contact with the interior of the bag. Water storage bags can also be inflated, coupled with one another, and used as water wings for swimming. Water storage bags are stowed in the equipment containers of rafts.

Dye Markers

The dye marker packet contains a small quantity of crystalline dye compound. When the compound is exposed to the water, it slowly dissolves while producing a brillant yellowish-green fluorescence. Under good conditions the dye is exhausted in 20 to 30 minutes and ceases to be a good target after an hour. The dye is visible at an approximate distance of 10 miles at 3,000 feet altitude.

An exterior orange-yellow envelope serves the purposes of: (1) providing a water-proof container for the dye compound in a loosely woven bag; (2) acting as an anchoring point for the dye pouch which is secured to a long tape; and (3) supporting a tape across the top of the envelope which is used to tie the marker to vests and other basic items of survival. The accessories container of each raft is supplied with 6 to 12 dye markers, depending upon the size of the raft. (See table 15-1.)

Emergency Signaling Code

The Ground Air Emergency Code was designed to establish an international means of communication by the use of symbols between survivors and search and rescue parties. Its instructions and illustrations, printed on tough water-resistant paper, outline a series of conditions relative to emergencies in connection with disabled aircraft, medical problems, landing instructions for the rescue party, etc. Strips of cloth, sticks, stones, or anything available may be used to create the symbols.

The importance of the code is illustrated by the number of survival items which are equipped with it. One copy of the code is inserted in the inspection data pockets of all parachutes. The chest type parachute loses its pack upon opening; therefore, the parachute is specially equipped with a code pocket located on the yoke of its lift web assembly. A copy of the code must also be made available for navigation chart boards and in places where chart boards are not used. The code may also be posted in the flight compartment of aircraft.

One copy of the code must be packed in all rafts as follows:

1. Pump pocket of multiplace rafts.
2. Inspection pocket of PK-2 and PR-2 rafts.

Desalting Kit

The desalting kit is used for making potable water from salt water. Each package of chemical (briquets), when mixed with sea water in the plastic bag, makes about 1 pint of drinkable water. Before the chemical kits were made available, fresh water was contained in pint-sized cans. The cans of water posed many problems. They were cumbersome, weighty, became undrinkable with age, and invited rust. Although the kits represent a great advancement, their potential is limited to the number of briquets that are packed in them. Therefore, it is of utmost importance to start the solar still as soon as possible after being downed at sea.

The desalting kit consists of a hinged metal container with a retaining lanyard, seven or eight wrapped desalting briquets, a length of mending tape, and a plastic bag for processing the water to be desalted. The briquets, processing bag, and mending tape are attached to a nylon tie tape, to each other, and to the metal container. The desalting kits are stowed in the emergency equipped container.

The vinylite bag should be rinsed to decrease the taste which passes into the treated water. This is done by filling the bag one-third full of sea water and rubbing the inner surfaces of the bag gently for 2 minutes, then rinsing several times with fresh sea water.

The chemical process is purposely adjusted to leave a little salt in the desalted water to compensate for perspiration losses. If a less salty taste is desired, a smaller amount of water can be used in the bag.

The procedure for using the desalting kit follows:

1. Close valve at the bottom and fill bag to line with sea water.
2. Take out one package of chemical and close container.

11170

Figure 16-26. —Magnetron spectral displays showing distortion.

Incorrect Operating Frequency

The trouble of incorrect operating frequency usually breaks down into two possible causes: (1) The magnetron may be defective; or (2) pulling may exist because of some fault in the RF system or from strong reflections from a nearby object.

When a new magnetron is inserted to correct off-frequency operation, it is not necessarily true that the original magnetron is defective. Individual constructional differences of magnetrons may vary, causing one to be pulled more easily by external conditions than another of the same type number. It is seen, then, that irresponsible replacement of apparently defective magnetrons may result in the rejection of good tubes. It is first necessary to check for the presence of pulling, to determine whether the magnetron actually is at fault. This check is made by measuring the VSWR of the RF system, with the slotted line placed as close to the magnetron as possible, or by feeding the magnetron output into a dummy RF load and rechecking the frequency. When off-frequency operation occurs with a low VSWR, the indication is that the magnetron should be replaced, unless, of course, it is of the tunable type.

Poor Spectrum

As was previously discussed, spectrum analysis is of considerable importance in the maintenance of radar systems. The reason for a poor magnetron spectral display or graph may be: (1) magnetron pulling, (2) magnetron pushing, (3) defective magnet, or (4) defective magnetron.

Magnetron Pulling

The test for magnetron pulling may be made by means of VSWR measurements or by the use of a dummy antenna, as mentioned above. Magnetron pulling may cause frequency shift, but this may go unnoticed if the frequency is still within the operating band.

Magnetron Pushing

A poor spectral display or graph is frequently evidence of magnetron pushing, and this fault is the result of improper modulator operation. When the output pulse is of imporper shape or amplitude, especially at lower power levels, excessive AM or FM may be present. The test applied to the modulator is made with the aid of a synchroscope and voltage divider. The voltage divider serves the purpose of reducing the modulator pulse to a usable amplitude. This amplitude is observed and multiplied by the appropriate factor. The pulse shape is observed and compared with available waveform charts. Under certain conditions, the magnetron may cause improper loading of the modulator, and thus introduce pulse distortion. The use of a dummy load for the modulator eliminates this condition. The modulator dummy load is a resistive impedance equal to the firing impedance of the magnetron; in most cases, a voltage divider is built into the test equipment to facilitate the measurement of pulse amplitude. This load replaces the magnetron during pulse measurements, and, therefore, helps to isolate trouble definitely to the modulator.

Defective Magnet

A poor spectral display or graph often indicates defects in the magnetron magnet. Low magnetic strength may result from careless handling. Improper mounting may cause the magnetic field to enter the magnetron at the wrong angle on magnetrons utilizing a separate magnet. Mounting difficulties are quickly found on inspection, and magnetic field strength may be checked by using a gaussmeter. Under some conditions, reversal of the magnet may improve the spectrum.

Defective Magnetron

A poor spectral display or graph may indicate defective magnetron. A weak magnet may cause

1114

3. Remove outer wrapping of briquet, tear off one end of transparent inner wrapping, and pour all of the chemical into the bag of sea water.

4. Fold the top of the bag down tightly, rolling it towards the buckle and strap to make a watertight seal.

5. Permit the chemical to stand in the bag for a few minutes, and it will disintegrate.

6. Further pulverize the chemical by kneading it gently for 15 minutes.

7. Shake the bag gently for 30 minutes.

8. To drink the water, unscrew the valve located at the bottom of the bag, being careful not to squeeze the bag. Put the tube in the mouth, and gently squeeze the bag or suck on the tube. Spit out the first few drops if too salty.

9. When finished drinking, close valve. The remaining water can be left stowed in the bag.

10. When all the water has been drawn from the bag, rinse out the chemical with sea water. The bag is then ready for reuse.

11. In case the bag becomes damaged, dry the affected area carefully and apply a patch of the mending tape provided.

If the plastic bag becomes damaged beyond repair, or is lost, the metal container can be used. In this case, fill the container to the line marked on the inside. Then add one package of the chemical and shake the can gently for 30 minutes. Drink the water through an emergency filter, made by holding a piece of cloth over the top of the can.

Solar Still

The solar still is used for the purpose of converting salt water to potable water. It is a reliable means by which man is assured an adequate supply of fresh water for long periods at sea. The still operates most effectively in direct sunlight, and will produce approximately 2 pints of water per day. It will also work on cloudly days if the weather is hot. The water obtained is fresh and pure, and although it may have a harmless plasticlike taste, especially when the still is first used, one can survive on it.

The first distilled water may be milky because of the talc which is sprinkled on the inside of the bag at the time of manufacture to keep the plastic from sticking together. In setting up a new still, throw away the first 2-hour output, because the chemical preservative used inside the new bag will be in the water. To drink the initial output might make one sick.

The solar still is a spherical-shaped envelope fabricated of vinyl plastic film and packaged in a vinyl plastic film container. On one side of the still is an attached towline with hook. The inflating tube and fresh water drain are attached at the bottom of the still. Stills are provided one per rated man-capacity of the raft.

The procedure for operating the solar still follows:

1. Wet the cloth drain on the bottom of the still. This prevents air from escaping through the cloth until the still is fully inflated. The cloth then acts as a safety valve so that the still cannot be overinflated. Excess air escapes through the cloth.

2. Inflate orally through the inflating tube until the still is round and firm as shown in figure 15-4. The suspension points should indent, indicating that it is properly inflated. Kinks in the inflation tube will prevent inflation.

3. Place the still in the water, and while holding it upright, fill the reservoir with sea water. When the ballast tube is full, the still will float in an upright position without being held. The reservoir should always be kept full.

PR.341

Figure 15-4.—Inflated still, showing suspension points.

41171

Refill when water drops to the lower mark on the cup. This should be necessary about once every 1 1/2 hours.

The salt is distilled from the water as follows:

The sun's rays heat the sea water on the black evaporator cloth stretched across the center of each still, causing evaporation. This vapor then condenses on the sides of the plastic cover in the form of beads which run down to the fresh water trap below the ballast tube. The salts, however, do not evaporate, but remain temporarily in the black cloth until washed out the drain at the bottom of the still. The cloth is self-cleaning and need never be washed.

When operating, the still has a silvery appearance which is caused by condensation of fresh water on the inside of the bag. If the upper half of the bag loses its silvery appearance in spots, pull on the string located in the cup to clear the water feed of foreign matter.

The still has to be topped off with air periodically. The bag should be sufficiently inflated at all times to prevent the cloth from touching the outer bag, because the bag will then become contaminated with salt from the cloth.

The bag may be deflated at night. If it is, turn it upside down until the water runs out and the ballast tube is empty. Rubbing the cloth at the bottom with a dry cloth makes the still easier to deflate when pressure is applied to collapse it. When the still is put in use the next day, it should be drained of fresh water after the first 15 minutes to remove any salt water which may have accumulated inside the still after it was deflated.

While the solar still is suprisingly strong in most respects it can be cut easily. Therefore, care should be taken to avoid having it come in contact with sharp objects. If the still is cut, it should be repaired immediately with the mending tape. This tape is applied in the same manner as adhesive tape.

Raft Paulin

The paulin furnished with rafts is used for weather protection, water collection, camouflage, as a signal, or as a sail attached to an oar.

The paulin is a rubber-coated (neoprene), nylon-base cloth. When laid out flat it is rectangular in shape. A reinforced hem around the perimeter of the paulin supports a series of grommets. The grommets are provided for utility purposes, making it possible to lace the paulin into many shapes for use as cover, sail, raincatcher, or anything else devised for the occasion.

The weatherproof tarpaulin is colored neon red (older paulins are orange-yellow) on one side and nonspecular blue on the other. The Mk 4 paulin is 72 x 108 inches.

The paulin may be rigged as a sail to speed raft movement or to navigate the raft in a desired direction. Care should be taken in strong winds to prevent capsizing. The paulin can be stretched across the raft to give protection from heat and cold. Rain for drinking purposes is collected in a pocket located in the center of the paulin. In signaling with the paulin, refer to the system illustrated in figure 15-5. To insure complete familiarity with these signals it is suggested that periodic drills be conducted in the actual use of the paulin for signaling.

Distress Signals

The Mk 13 Mod 0 distress signal is used for day or night distress signaling. The signal may also be used to give wind drift information to helicopters performing pickups of downed personnel.

The Mk 13 Mod 0 distress signal is a pyrotechnic torch that burns approximately 18 seconds. It produces a red glow for night use and orange smoke for day use. Before igniting, select the signal (day or night) to be used.

The night flare can be identified in the dark by a series of small beadlike projections that are embossed around its circumference. After selecting the flare to be used, the sealing tape should then be torn off from around the end of the cylinder and the paper cap removed. Figure 15-6 illustrates the step by step procedures for using the Mk 13 Mod 0 distress signal. Grasp the pull ring and flip it over the rim of the signal case as shown in 15-6 (B). Press down the overhanging ring with your thumb until the seal snaps, as shown in (C). If the seal refuses to snap with this kind of force, continue pressing on the ring so that it bends over the rim and against the signal body as shown in (D). Flip the bend ring back to the top of the signal and press down (E), using the bend pull ring as a lever. After the seal breaks, point the signal away from your face and body and give a sharp yank on the pull ring. Hold the signal at an angle of approximately 45° from the horizontal with your arm fully extended. Care should be

11172

PR.342

Figure 15-5.—Paulin signals.

taken not to drop any of the contents on the user or the raft. After one end of the signal has been expended, it may be cooled by immersing in water and then saved until both ends have been used. The distress signal should be cool before being stored.

Illumination Signal Kit

The Illumination Signal Kit Mk 79 Mod 0, is a hand held signal used for day or night signaling by ground personnel or as a distress signal by downed pilots and aircrewmen.

PR.343

Figure 15-6.—Igniting the Mk 13 Mod 0 distress signal.

SVIII 11175

Each kit consists of one surface signal projector Mk 31 Mod 0 and seven hand fired signals Mk 80 Mod 0, inserted in a bandolier, as shown in figure 15-7.

The signal projector projects a 12,000 candlepower, red star, hand fired signal to altitudes in excess of 200 feet. It contains a lanyard for attaching the signal projector and bandolier of cartridges to the clothing of the pilot or aircrewman.

OPERATING INSTRUCTIONS.—Operating instructions for the Mk 79 Mod 0 kit are as follows:

1. Pull trigger screw into angular safety slot.
2. Mate projector with signal and rotate to right until signal is seated.
3. Hold projector, arm fully extended overhead.
4. Grip projector firmly. With snapping thumb action, pull trigger from safety slot and release into firing slot.
5. If signal misfires, at least one more attempt should be made to fire the signal.

First Aid Kits

One first aid kit is used with each of the multiplace rafts and is stowed in the emergency equipment container. The kit is installed when the raft is put in commission. The directions for the emergency use of the medicine and equipment can be found inside each first aid kit.

The first aid kit is a Bureau of Medicine and Surgery item.

Sunburn Ointment

Sunburn ointment is provided in a small container and should be stowed in the emergency equipment container to prevent if from deteriorating.

The sunburn ointment should be applied to all parts of the body that are exposed to the sun. For most effective results, rub the ointment well into the skin. The ointment can be used in this same way to give protection from windburn in cold areas.

PR.344

Figure 15-7.—Illumination Signal Kit Mk 79 Mod 0.

1174

Rations

Tablet rations are contained in a pneumatically sealed can which can be opened with the key provided. Each unit contains the following:

5 sucrose citric acid tablets
10 sucrose lipid citric acid tablets
2 multivitamin tablets
2 sugar-coated chewing gum tablets
1 waterproof bag and 2 slips for the purpose of preserving unused portions of the rations.

One can of rations should be supplied for each man for which the raft is designed to accommodate. The rations are stowed in the emergency equipment container.

PACKING THE MK 4

Rafts must be properly folded, rolled, and packed; then stowed in the location prescribed in the aircraft flight manual. This will render them ready for immediate use in the event of an emergency over water.

The following procedure for packing applies to the Mk 4 and multiplace rafts in general:

1. Store all accessory and emergency equipment in the containers provided. Seal the supply pockets and the emergency equipment container by closing the slide fastener and sealing with a strip of tape, type R, 1 5/8 inch wide.

2. Attach a fully charged CO_2 cylinder of the proper size and type (as prescribed in Special Aeronautic Requirements-375) to the inflation manifold and store in the cylinder carrier. Connect raft retaining line to the neck of the cylinder.

NOTE: Inspect the safety wiring of the pull handle for compliance with NavAir 13-1-6.1. This must be done before the raft is packed. If the wire is broken, reweigh the CO_2 bottle and safety-tie.

3. Completely deflate the raft, using a suitable vacuum pump (the common household type vacuum cleaner is adequate). Open the topping-off valves and apply suction. As each flotation chamber is deflated, close the valve while still applying suction.

WARNING: A raft which is not completely deflated is difficult, if not impossible to pack properly, and in addition, poses a serious problem to the efficiency of the aircraft involved, due to expansion of the trapped air at high altitudes.

4. To prevent the folds of rubberized fabric from sticking together, the entire raft must be dusted with talc. Give particular attention to the area under the flotation tubes at the junction of the flotation tube and the raft bottom. This talc acts as a mild abrasive and assures a smoother and more positive unfolding action when the raft is being inflated.

5. Check the raft righting handles and the sea anchor retaining line for entanglement.

6. Inspect the emergency and accessory equipment containers for contents as listed in table 15-1. Replace any item which is missing or damaged. Check for security of retaining lines.

7. The words "Lash all equipment to raft to prevent loss" should be stenciled inboard of the top centerline on the flotation tube using black, 1-inch letters. Other paint and markings on rafts which are illegible or otherwise unreadable should be restored.

8. Lay out the raft case and inspect it for signs of wear, abrasion, rips, tears, or deterioration from acid or other damaging agents. Check the snap fasteners for operation and general condition (replace as necessary). Talc inside of case.

9. Position the accessories container in the center of the raft with the top end of the container in line with the valve of the CO_2 cylinder. (See fig. 15-8.)

10. Figure 15-9 illustrates the proper method of folding and rolling the Mk 4. Keep the raft retaining line and the emergency equipment container retaining line clear and positioned so that the emergency equipment container line

PR.345

Figure 15-8.—Position of the accessory container.

11175

PR.346

Figure 15-9.—Folding and rolling the Mk 4.

emerges from the packed raft on the end opposite the CO_2 valve and the raft retaining line, attached to the CO_2 valve, emerges from the same end of the case.

11. After making the top fold and before starting to roll the raft, coil or fake the sea anchor retaining line on the top fold and place the sea anchor over this line.

12. Roll the raft, starting from the side with the CO_2 bottle attached. Leave the valve of the CO_2 bottle forward of the folds of the raft to permit it to emerge from the center of the end of the carrying case after the raft has been completely packed.

13. An inspection and packing data card should be signed by the person responsible for the work accomplished. This tag should be attached to the neck of the CO_2 bottle, so as to be visible at all times without unpacking the raft.

AR-4 DROPPABLE BOAT

The AR-4 droppable lifeboat is a four-man pneumatic boat of double tube construction. In the packed condition, the assembly is 41 inches in length and 16 inches in diameter. The total weight is approximately 105 pounds.

It is designed to be dropped from the bomb bays or bomb racks of aircraft at altitudes of 100 to 150 feet and at an indicated airspeed of 100 knots. It may also be carried within the fuselage of large aircraft and dropped by hand from hatches. Two adjustable supporting straps are supplied with the container so that the unit may be slung torpedo fashion between the bomb racks. These straps are attached in such a manner that in the event that only one bomb rack is released, the strap will pull free from the container and not impede the fall of the assembly.

The boat is complete with a sailing rig, mast, rudder, keel, weather shield, sun canopy, sea anchor and inflatable floor. The two-compartment, removable, inflatable floor is inflated through the topping-off valves provided, with a handpump. The floor is designed so that will not chafe the flotation tube of the boat. Removed, it can be used as an auxiliary means of flotation.

Figures 15-10 and 15-11 illustrate the AR-4 lifeboat.

An instruction booklet is stowed in the starboard bow pocket of each assembly. The booklet contains complete instructions for operating the boat.

CO_2 SYSTEM

Only the main flotation tube is inflated with CO_2. The remaining inflation chambers must be inflated with handpumps. A wrench, suitable for detaching the CO_2 cylinder from the boat, is securely attached adjacent to the cylinder.

SAILING RIG

A mast yardarm is formed from sections of oars which are the same as those used in the standard type multiplace rafts. Oar sections necessary for forming the mast yardarm are as follows:

Oar and section	No. required
6-ft oar (Section A).....	2
6-ft oar (Section B).....	6
6-ft oar (Section C).....	2

11176

1. CO_2 valve cable.
2. Weather shield.
3. Weather shield tiedown.
4. Patch for sheet lead.
5. Motor mount buckle straps.
6. Fabric loops for motor mount.
7. Rudder lock.
8. Socket to receive oar length.
9. Lifeline patch inboard.
10. Sleeve for mast insertion into keel.
11. Inflatable floor.
12. Valves for two-compartment floor.
13. D-ring for bow mast stay.
14. Stowage pockets.
15. CO_2 hose assembly.
16. D-ring for starboard mast.
17. CO_2 cylinder and valve.
18. Sea anchor bridle.

PR. 347

Figure 15-10.—AR-4 lifeboat (basic plan).

The mast is made up of 1 section A length and 2 section B lengths. The yardarm consists of 1 section A length and 4 section B lengths. Section C lengths are used with any of the other sections when paddles are needed.

MAST STAY AND HALYARD FITTING

One wooden fitting is supplied to fit the top of the mast to hold the three mast stays and receive the halyard as shown in figure 15-11.

The D-ring assemblies for the mast stays consist of 1 1/4-inch cadmium-plated D-rings secured to type O fabric patches by lengths of nylon webbing 1 inch wide, passed through the ring, and stitched to fabric patches. These rings, when installed, must be able to withstand a straightaway pull of at least 300 pounds.

The mast halyard cleat is a metal cleat designed for attachment by clamping to the mast. It is used for securing the sail hoist and yardarm securing lines.

SAIL, RUDDER, AND MOTOR

The sail material is made from 2-ounce sailcloth. Its color is blue, and the sail is equipped with a fabric sleeve to receive the yardarm. A collapsible wooden rudder folds in half, lengthwise, through the middle on hinges. No motor is supplied with the assembly; however, it is equipped to receive one of low horsepower.

MARKINGS ON THE RAFT

When markings become obliterated, consult NavAir 13-1-6.1 for information that will direct

PR.348

Figure 15-11.—AR-4 lifeboat (rigged for sailing).

the proper phrasing, size of the letters, paint or other liquid vehicle to use, and the location of the instructions to be reapplied.

MISCELLANEOUS EQUIPMENT

The following is a list of the miscellaneous equipment for the AR-4:

1. Hand pumps. Two plastic hand pumps are supplied for emergency inflation.
2. Nylon cord. The supply pocket contains 100 feet of type I nylon cord, which is intended for general utility purposes.
3. Whistle. One police type whistle is provided.
4. Bailing sponge.
5. Bailing buckets. Two bailing buckets, constructed of type N fabric, are supplied with each boat.
6. Jackknife.

EQUIPMENT CONTAINERS

Two equipment containers are supplied with each boat. One is used to contain the following sailing equipment; Sail, mast, and yardarm sections; mast stay and halyard fittings; and rudder assembly. The other container holds all other items of equipment, except the sea anchor, instruction booklet, and bailing buckets. The contents are marked on the containers in 1/4-inch letters.

CARRYING CASE

The boat is packed in the carrying case. The outer color of the case is orange yellow. The case consists of an outer ply of type II fabric (in accordance with specifications) backed up by a ply of 8-ounce cotton duck. The ends are closed by snap fasteners. The longitudinal opening is enclosed by a locking pin-and-cone assembly attached to the CO_2 valve by a snaphook fastener. This assembly is covered by a fabric flap, closed by snap fasteners. A pull on the valve cable releases the locking pins on the case before actuating the CO_2 valve. Two webbing straps are provided to suspend the unit from aircraft bomb racks. Each strap is made from webbing 2 inches wide (400-pound minimum breaking strength) equipped with a parachute harness V-ring on each end. Each strap is also equipped with buckles for adjustment. The maximum length of each strap assembly

11178

extended is 65 inches. A V-ring is installed at one end of the case at the base of the opening.

SEA ANCHOR

One sea anchor is supplied with each raft, attached by a bowline knot to its mooring patch. The sea anchor must not be rolled inside the boat, but must be stowed in the boat carrying case, thus permitting the sea anchor to fall into the water upon inflation of the boat. When packing, care must be taken to insure that the bowline does not foul and bind the boat during inflation.

EQUIPMENT STOWAGE

Table 15-2 illustrates where the additional equipment is stowed in the AR-4 assembly; and also where the equipment previously described is stowed.

Packing the Equipment

The bailing buckets are stowed in the port bow pocket. All rigid parts must be wrapped individually with cloth or felt paddings to protect the parts and the raft fabric from damage. The mast and oar sections must be secured together and be padded at both ends. The equipment containers are stowed adjacent to the CO_2 cylinder, one on each side of the cylinder, and each container is secured to the inside lifeline by a 6-foot length of type III nylon line.

The metal parts of the manifold and the CO_2 cylinder valve must be wrapped carefully with wads of cheesecloth or felt. The cylinder must also be padded at both ends. The CO_2 cylinder assembly is the heaviest single item of equipment for its size, and must be prevented from damaging the boat when the unit is dropped at or below 100 knots indicated airspeed.

All metal parts, such as D-rings, buckles, valves, etc., must be wrapped securely with cloth or felt padding.

The rudder is collapsed completely, bound together, and stowed (well-padded) in the equipment container.

FOLDING THE LIFEBOAT

First of all, the boat must be deflated completely. Then spread the boat flat so that gear may be stowed on it. Fold each side toward the middle and on top of all stowed gear. The CO_2

Table 15-2.—AR-4 lifeboat equipment.

24. Nylon cord (type I)	100 ft	
25. Emergency signaling code.	2	

actuator control cable must fall on top of the starboard fold in such a manner that it can be operated after the boat is rolled.

Roll the boat from each end toward the CO_2 cylinder at the center. When rolling from the bow to the cylinder, care must be taken in that the keel cable does not foul during the inflation of the boat. The cable is held as near as possible to the center of the bottom during the rolling operation. The keel must be extended flat on one side. The CO_2 actuating control must be kept clear.

The boat is placed in the carrying case, folded and rolled, with the open portion up, and alined with the carrying case opening. This is to assure that the boat will float and inflate right side up on the water. After this, the case is closed as the releasing assembly is engaged.

INSPECTION TESTS

A system has been adopted whereby inflatable equipment will be functionally tested, with carbon dioxide inflation, upon issue and every fourth inspection cycle thereafter. The intervals between aircraft calendar inspection cycles must not exceed 22 weeks.

Functional Test

Insure that the area surrounding the raft is clear of foreign objects. Inflate the raft with the installed carbon dioxide inflation system so that the raft inflates to the design shape and to ascertain that all parts of the inflation assembly perform properly.

Leakage Test

Insure that all of the carbon dioxide installed in the raft during the functional test is completely removed, using a rotary vacuum pump. If a rotary vacuum pump is not available, a vacuum cleaner may be used.

Inflate the compartments of the raft with air until the compartments are inflated to the pressure indicated in table 15-3.

Allow 15 minutes for the raft pressure to stabilize and adjust the pressure if necessary to the original pressure of 2 psi. Allow the raft to remain inflated for 4 hours, then read and record the pressure. If the pressure of the raft is below the pressure required in table 15-3 under the minimum pressure column, inflate the raft to leakage test pressure and coat the compartment with a soap solution to locate the leak. Mark the leak area and rinse with clean water, air dry, and make repair.

Inspection of Physical Condition of Raft, Container, and Case

This task may be done concurrently with the leakage test. To inspect the raft, container, and case, proceed as follows:

1. Inspect all the seams, including those joining the flotation tube to the raft floor, for proper adhesion.
2. Inspect the raft floor for tears and punctures.
3. Apply a small amount of soap solution to the inlet valve and manifold and inspect for leaks; also inspect the valve and manifold for damage, wear, and corrosion.
4. Check the operation of the topping-off valve by opening it to partially deflate the raft and then close the valve. Apply a small amount of soap solution to the valve to insure that it has properly seated.
5. Inspect all patches, pockets, handles, nylon lines, sea anchor, and all other parts for sign of wear, damage, tears, security of attachment, and proper adhesion. Inspect all the hardware for proper operation, corrosion, and security. Make any necessary repairs.
6. Compare the markings illustrated in NavAir 13-1-6.1 to the raft being inspected to insure proper location, context, and legibility. Restencil the raft if necessary.
7. Inspect all accessories and survival items for damage, excessive wear, corrosion, expended contents and expiration of service life. Replace the items as necessary.

Modular Requisitioning of Equipment

Inflatable survival equipment and accessories are no longer procured as an assembly. Instead, the components making up an assembly are individually procured. For example, when the one-man raft was previously requisitioned from stock, the inflation valve, carbon dioxide cylinder, outer container and, in most cases, survival items were included. Under the new system if a raft is requisitioned, only a raft will be provided. If an inflation valve is required, it must be requisitioned separately.

181 11180

the magnetron imput to exceed rated values; if so, continued operation will result in a damaged unit. Missing lines in the spectral display are the result of magnetron arcing, and, if excessive, may completely destroy the shape of the spectrum. New magnetrons display moderate arcing until seasoning is completed, and, therefore, should be allowed a sufficient breaking-in period before the spectrum is analyzed. As mentioned previously, the end of the useful life of a magnetron is characterized by an increase in arcing and general instability. When the output power is low, it usually indicates a weak magnetron or a low modulator output. This uncertain condition may be resolved by testing the modulator output pulse; normal pulse indicates that the trouble is in the magnetron.

RECEIVER SENSITIVITY

The performance of a radar receiver is determined by several factors, most of which are evolved and established in the design engineering of the equipment. In the paragraphs to follow, only those which are concerned with maintenance are considered. The more important factors are receiver sensitivity (which includes noise figure determination and minimum discernible signal (MDS) measurement), TR recovery time, receiver recovery time, and receiver bandwidth.

Many radar receivers have circuits which are designed to serve a special function. Three of these special circuits commonly encountered are instantaneous automatic gain control (IAGC), sensitivity time control (STC), and fast time constant (FTC). These circuits may be found in combination or singly, depending upon the purpose of the radar. In the test methods and procedures described herein, the special functions should be disabled. The automatic frequency control (AFC) circuit may be permitted to operate during the receiver tests. A good check on the AFC is to make the tests specified for manual tuning, then switch to AFC. If the AFC circuit is normal, the signal indications will not change.

Inefficient range performance of a radar system can be caused by troubles in the radar receiver. This is due to the great number of adjustments and components associated with the receiver. Loss of receiver sensitivity has the same effect on range as a decrease of transmitter power. For example, a 6-db loss of receiver sensitivity shortens the effective range of a radar just as much as a 6-db loss in transmitter power. Such a drop in transmitter power is very evident in meter indications and, therefore, is easy to detect. On the other hand, a loss in receiver sensitivity, which can easily result from a slight misadjustment in the receiver, is very difficult to detect unless accurate measurements are made.

Figure 16-27 shows a comparison of radar system performance versus maximum range. The loss of system performance in db includes both transmitter and receiver losses. It should be noted that with a loss of 5-db in both receiver and transmitter (total of 10-db) performance, only 55 percent of the system's maximum range is realized.

The sensitivity of the receiver determines the ability of the radar to pick up weak signals. Greater sensitivity indicates that the receiver can pick up weaker signals. Sensitivity is measured by determining the power level of the MDS. MDS is defined as the weakest signal that produces a visible receiver output; its value is determined by the receiver output noise level which tends to obscure weak signals. It follows, therefore, that an MDS level is dependent upon the receiver noise level. (See Basic Electronics for a discussion on noise in amplifier circuits.)

The measurement of a minimum discernible signal consists of measuring the power of a pulse whose level is just sufficient to produce a visible receiver output. If a radar receiver has the specified MDS level, the noise figure should be correct also. Therefore, measurement of the MDS is a satisfactory substitute for a noise-figure determination, and is less complicated. When readings are taken for comparison purposes, correct pulse length must be used. Maintenance instructions for the radar set will usually specify the pulse length to be used in receiver sensitivity tests. In most cases it will be the same as the transmitter pulse.

Figure 7-28 (chapter 7) shows a simplified block diagram of the AN/UPM-32 test set connected for signal generator operation. When the test set is operated as a signal generator, the test set klystron oscillator supplies FM, pulse-modulated, CW, or externally modulated microwave signals.

The klystron oscillator output passes through the uncalibrated variable attenuator to a microwave tee. At this point the power splits evenly in both directions. One-half goes to the power monitor for the reference level indication and the other half passes through the calibrated variable attenuator to the RF connection and

1115

* Compartments may be tested simultaneously.

MK 7 RAFT

The Mk 7 raft is basically the same in design as the Mk 4, except in size and amount of equipment carried. It is 12 feet long and 5 feet 8 inches wide when inflated. Its gross weight when packed (including the CO_2 system with all equipment) is 114 pounds. The internal volume of the CO_2 cylinder is 205 cubic inches, and the CO_2 charge required to inflate the raft to 1 psi is 4.70 pounds. The raft provides a maximum buoyancy of 2,500 pounds.

EQUIPMENT

The Mk 7 is designed to accommodate seven survivors and carries accessory and emergency equipment to sustain this number for 7 days. This equipment is listed in table 15-1.

PACKING

Attach a fully charged CO_2 cylinder to the inflation manifold. NOTE: Check pull cable for compliance with NavAir 13-1-6.1. Stow equipment, dust entire raft with talc, and position raft case in the same manner as with the Mk 4.

At a point as near the filler manifold as possible, fold the bow section over the stern. At approximately 35 inches from this fold, fold the bow section back over itself. The stern section is then folded over the raft and back again to make the folded width of the raft about 35 inches.

Beginning on the side with the CO_2 bottle, roll as tightly as possible. (See fig. 15-12.) Complete the packing in the same manner as for Mk 4.

MK 12A-1 RAFT

The Mk 12A-1 inflatable raft is intended for use as emergency survival equipment for survivors of transport type aircraft forced down at sea. It consists of two buoyancy chambers (main and upper flotation tube) mounted one upon the other, with a raft body.

The raft is equipped with an inflatable seat, two removable inflatable floors, and a canopy.

11181

PR. 349

Figure 15-12. —Folding and rolling the Mk 7 raft.

11182

The canopy is used for protection from the elements. The inner surface of the canopy is blue, for use when camouflage is desired, and the outer surface is fluorescent red to attract rescue craft. It is attached around the outer perimeter of the upper floatation tube and supported over the raft by aluminum bows (ribs).

Initially, the main flotation tube is inflated with CO_2 and a hand pump is provided to inflate the seat, floors, and upper flotation tube through topping-off valves. As an extra precaution against loss of the raft due to an inadvertent rupture of the flotation tubes, internal bulkheads divide the main flotation tube vertically amidships, forming two separate compartments of equal volume.

EQUIPMENT

Survival equipment sufficient to keep 12 men alive for 7 days is carried in the Mk 12A-1 raft. This equipment is listed in table 15-1.

PACKING

The raft is completely deflated as described for other multiplace rafts, and folded and packed as shown in figures 15-13 and 15-14. The raft is then placed in the carrying case with the axis of the CO_2 cylinder running in the same direction as the length of the case. The end of the cylinder containing the ripcord static line is properly attached to the cylinder inflation valve, the ripcord pins are inserted through the release cones, and the flaps are snapped.

OPERATION

To inflate a raft packed in a carrying case, lift the flap on the end of the case, and pull the ripcord handle out until free. The handle is attached to the carrying case and actuates the inflation valve.

Automatic inflation of rafts installed in aircraft compartments is accomplished by means of a control cable attached to the compartment latching mechanism and to the spring type snap on the end of the CO_2 cylinder valve release cable. The control cable is attached to a release handle inside the aircraft. A sharp pull on this handle first releases the latch of the raft compartment door, then actuates the inflation system. Rafts so installed are not packed in carrying cases.

MK 20 RAFT

The Mk 20 inflatable raft is made by mounting two buoyancy chambers of rubberized fabric (one upon the other) and suspending a floor between the two chambers. The chambers are divided into a main flotation compartment and a boarding station compartment by two internal vertical bulkheads.

The raft is designed to be right-side-up from either side. This is accomplished by positioning the topping-off valves so that they are accessible from either side and by placing the boarding stations (one on either side) directly opposite each other. Incorporated in the floor is an inflatable floor support which will maintain a horizontal position for a fully loaded raft.

The flotation compartment and boarding ramps are inflated by CO_2 and the inflatable floor support is inflated with the hand pump. An equalizer tube is provided between the two main flotation compartments to distribute the gas equally. NOTE: The equalizer tube must be open when the raft is packed for use.

OPERATION

To inflate the raft when packed in the carrying case, lift flap on the end of the case and pull the ripcord handle out until free. The handle is attached to the static line which opens the carrying case and actuates the inflation valve.

WARNING: Hold the retaining line fast to prevent loss of the raft and equipment during actual inflation.

A full charge from the cylinder inflates the raft to approximately 1.25 psi. The initial pressure of the gas in the raft may be low, but will increase until ambient (surrounding) temperature is reached, then the pressure in the raft will be 1.5-2.20 psi. This process usually takes about 5 to 10 minutes. If the raft is underinflated after a 10-minute wait, attach the hand pump to the appropriate topping-off valve and inflate to the desired pressure. Inflate the boarding stations with the hand pump immediately after all personnel are aboard the raft.

Automatic inflation of the Mk 20 is identical to the Mk 12A-1, described earlier.

PACKING

Prior to packing, inspect CO_2 cylinder for safety wiring of the inflation gear assembly, in

PR.350

Figure 15-13.—Folding the Mk 12A-1 raft.

accordance with instructions contained in Nav Air 13-1-6.1. Inspect the floor for stenciled instructions for erecting the canopy. These instructions must be legibly stenciled in 1/2-inch letters.

There are two different types of CO_2 cylinder actuating systems in use with the current Mk 20 raft; the direct pull and the indirect pull. The direct pull will be discussed in this chapter.

11184

PR.351

Figure 15-14.—Folding and rolling the Mk 12A-1 raft.

PR.352

Figure 15-15.—Packing the Mk 20 raft with the direct pull CO_2 for installation in the carrying case.

When packing the raft in the carrying case, it must be completely deflated and the cylinder attached and packed as follows:

1. Fold both boarding ramps inboard as shown in step 1 of figure 15-15.
2. Continue folding the raft as shown in steps 2 and 3, so that the fold line is between the pull handle circular plate and cylinder manifold.
3. Continue folding the raft as shown in steps 4 and 5. Maintain a maximum width of 35 inches when folding the raft.
4. Bind the two handles of each equipment container together with one end of an 18-foot retaining line, using a bowline knot. Use a separate 18-foot line for each container.
5. Place the two equipment containers on top of each other approximately 35 inches in from the raft end opposite the CO_2 cylinder (step 6).
6. Secure the free end of each equipment retaining line to the outboard lifeline.
7. Fold the end of the raft over the equipment container and roll the raft toward the cylinder.
8. Place the raft in the carrying case so that the cylinder is parallel to the length of the case, and directly under the closing snaps on top of the case. Adjust the cylinder so that the circular plate and metal pull handle will project from the case.
9. Fake the excess retaining line from the CO_2 cylinder and secure it with two rubber bands. Place the line inside the case and close all the snaps. Secure the retaining line snap hook to the metal pull handle on the cylinder plate.

Instructions for packing the Mk 20 raft with the indirect pull CO_2 cylinder as well as the direct pull cylinder can be found in NavAir 13-1-6.1; see also figure 15-15.

Installing for Ejection

In lieu of packing the Mk 20 in a carrying case for manual toss-out and inflation, the raft may be packed and installed in a compartment for ejection. The following steps apply to folding and installing the Mk 20 raft for ejection:

11182

1. Place the raft on a flat surface after it has been completely deflated. Because of the size of the raft, a large well-cleaned area of deck is the best place for packing. The position of the inflating cylinder will determine whether the raft is stowed in a left- or right-wing compartment. If the cylinder is facing the wrong direction, turn the raft completely over.

2. Fold the raft in thirds so that the cylinder remains at the end of the raft. (See fig. 15-16.)

3. Fold back one-half of the top fold.

4. Make five folds in accordion pleats so that the cylinder is resting on top of the rectangular bundle.

5. Set the raft into the proper compartment. (See fig 15-17.) The operating head of the raft cylinder must face inboard with the cylinder of the aft side of the compartment. Place the cylinder on the supporting rack. The accessory container may be placed in the bottom of the compartment before the raft is stowed, or on top of the folded raft.

6. Connect the release cables at the quick-disconnect fittings.

7. Connect the raft lanyard to the raft lifeline, and place the bag holding the lanyard on top of the raft.

8. Close and latch the compartment door or cover.

9. Turn the adjusting screws on the cylinder support rack so that the cylinder is held tightly against the compartment cover.

MAINTENANCE OF RAFTS

All personnel engaged in the handling, inspection, or maintenance of rafts must exercise caution to avoid stepping on or placing any unnecessary objects or items on top of them. Persons engaged in maintenance or repair of unpacked rafts must not step on any part of the raft while wearing shoes, nor on any part of the flotation tubes at any time. Rafts must not be thrown around or dropped since this may cause damage to the raft or its accessories. Particular care must be exercised to prevent hydrocarbons such as gasoline, oil, or grease from coming in contact with any part of the raft or its equipment.

Repairs

Personnel engaged in the repair of rafts and other rubberized flotation equipment must be thoroughly familiar with NavAir 13-1-6.1 and know the various types and uses of cements as well as the correct procedures to be followed when making necessary repairs to this equipment.

TYPES OF CEMENT.—The preferred cement used in the repair of pararafts and multiplace rafts is MIL-C-5539A, class 3; if not available, MIL-C-5539, type B may be used.

PATCHING PROCEDURES.—For patching holes in multiplace rafts cut a round or oval patch of rubber-coated nylon cloth approximately 2 inches larger in diameter than the damaged area. Scallop the edges of the patch if larger than 5 inches in diameter. If the damaged area is larger than 1 inch in diameter or length, both the inside and outside must be patched.

Raft patching procedure is as follows:

1. Place the patch over the damaged area and draw an outline of the patch on the raft or preserver.

2. Clean the underside of the patch and the area to be patched with four applications of toluene. Apply toluene with back and forth strokes on the first and third applications and one-way strokes on the second and fourth applications. Allow the patch and damaged area to dry between applications. NOTE: Do not touch cleaned area when handling.

3. Mix equal amounts of cement and toluene. Apply the mixture to the underside of the patch and outlined area on the raft with a soft-bristle brush. Allow the area to dry for approximately 10 minutes.

4. Apply a second coating of the mixture to the damaged area and the patch and allow them to dry for approximately 10 minutes.

5. Apply two coatings of unthinned cement to the outlined area on the raft and patch. Allow the cement to dry for approximately 10 minutes after the first coating.

6. Place the patch over the damaged area when the second coating of unthinned cement has become tacky. If the damaged area is a slit or tear, butt both edges together before applying the patch. Roll out any air bubbles with a wooden roller.

7. Allow the cement to set for 24 hours, then perform the leakage test.

8. If necessary, paint the patch with rubber base paint to match the color of the raft. Apply talcum powder to the patch after the paint has dried.

9. The repair of seams can be found in NavAir 13-1-6.1.

11186

PR.353

Figure 15-16.—Packing the Mk 20 raft for installation for ejection.

Emergency Repairs

Emergency repair of the Mk 20 raft, when in the water, is accomplished by the use of the metal clamp type plugs provided in the accessory equipment container of each raft. No emergency repair equipment is provided with other types of rafts.

11187

PR.354

Figure 15-17.—Placing the folded raft into the compartment.

Safety Precautions

Cements and solvents are flammable materials and must be treated as such. Never smoke nor permit any type of open flame near cements or solvents when they are being used. After completion of any repair work involving these materials, always replace caps or covers as tightly as possible. The container should be stored in a cool storeroom. Common sense and a few precautions will avoid many accidents. WHEN WORKING WITH CEMENTS AND SOLVENTS, DO SO IN A WELL-VENTILATED SPACE.

Survey of Rafts

Liferafts must be forwarded to Supply or surveyed in accordance with the Naval Supply Systems Command Manual when any of the following conditions exist:

1. Split, open, or leaky tube seam or tube seam tape.
2. Porous areas on tube.
3. Leakage test failure not resulting from a cut, tear, or puncture.
4. Extensively damaged floor.
5. Damaged, malfunctioning, excessively worn, or corroded inlet valve, oral inflation valve, oral inflation tube, or topping-off valve.
6. Internal bulkhead leak.
7. Cracked or excessively corroded manifold.

STOWAGE OF RAFTS

Pneumatic survival equipment of any kind should never be stowed near hot places, batteries, auxiliary powerplant, stoves, inverters, or the like. Frequent inspection and occasional discipline will also be necessary in order to detect and stop pilferage of the contents of stowed rafts. Nonflying squadron personnel must be made aware of the dangers which may result from pilferage.

Rafts carried in aircraft not equipped with raft compartments should be stowed in the fuselage in a manner and position that will render them readily available. This will save much valuable time for personnel in abandoning the aircraft during a ditching. Rafts stowed in the fuselage should retain their carrying cases.

Because of the nature of materials used in raft construction, both flight and maintenance personnel should avoid sitting on rafts or placing heavy tools or other equipment on them.

DEMONSTRATING THE USE OF RAFTS

Many ditchings and water crashes occur in a rough sea or at night. Only complete familiarization with the use of survival equipment will give the aircrewman a chance of survival under such adverse conditions. Therefore, intensive drill in the use of rafts and their associated equipment is essential for safety.

The survival officer will be concerned with survival techniques and should see that a survival training program is set up in the parachute loft. In most cases, the chief-in-charge of the loft will have the responsibility of setting up this training. As a PR3 or PR2 you will have many occasions to participate in this training, and in many instances may be completely responsible for the carrying out of the program. Regardless of who is in charge and must shoulder the complete responsibility, it is the duty of every PR to be completely familiar with all

11188

phases of survival training and be able to demonstrate the use of survival equipment.

A very effective system of training in water survival techniques is the use of the Dilbert Dunker to simulate an actual aircraft ditching as closely as possible and to teach the best escape procedure with full equipment.

Although such complete courses of training cannot be conducted in certain localities because of the lack of specialized equipment, the PR should make every attempt to give aircrewmen frequent practice in the actual use of the equipment. Discussions, demonstrations, and shop lectures are all helpful, but working with the actual raft equipment is the only way to acquire the knowledge essential to survival.

Inflating the Raft

In demonstrating the raft's use, the most important thing to stress is that the retainer lanyard snap is firmly attached to the ring on the lifevest before inflating the raft. Inflate the raft as soon as possible so that personnel can get out of the water. Inflation of the raft is effected by pulling on the short length cable attached to the CO_2 cylinder valve. After several hours, the CO_2 cylinder may be removed from the side of the raft. It tends to chafe the side of the compartment and acts as an anchor, causing the raft to orbit around it. Sometimes it is possible to back off the coupling between the cylinder and the manifold so that the cylinder releases from the mount. Once the cylinder has been removed, it will no longer be useful in any way and should be thrown over the side. This, of course, is under actual emergency conditions; in a training demonstration, the cylinder should be saved and recharged for further use on the training equipment.

In demonstrating their use, instructions should also be given on manual inflation of rafts. If nothing happens after the CO_2 cable has been pulled, the carrying case should be pulled off and the raft unfolded so that the hand pump in the oar pocket will be accessible. After the pump is removed, the first compartment to be inflated should be the seat. This will help keep the raft afloat so that the remaining compartments can be inflated with the pump. In attaching the pump, care must be taken not to screw the pump too tightly to the valve. If it is too tight, it may freeze and be impossible to loosen without some type of wrench or pliers.

Boarding the Raft

The best way to board the multiplace raft is to grasp the boarding handle, kick feet vigorously while pulling elbows and lifevest over the raft tube. Then grasp the inboard boarding handle, and pull and roll the body into the raft. Another way of boarding the raft is illustrated in figure 15-18. This method is more satisfactory when boarding the LR-1 liferaft. Boarding by going over the end rather then the side, lessens the possibility of capsizing the raft.

If the raft should capsize, it is best to approach it from the side on which the CO_2 cylinder is installed. The survivor reaches across the raft and grasps the righting handle farthest from the cylinder. Then, by sliding back into the water and pulling on the righting handle at the same time, the raft will turn right side up. By this method, there will be no chance of the CO_2 cylinder hitting the survivor when he rights the raft. (See fig. 15-19.)

Another important point to remember in righting the raft is to note the surface winds and take advantage of them. It is very hard to right a raft against the wind.

Safety Precautions in Boarding Rafts

Extreme care should be taken when boarding rafts or assisting personnel into the raft from the water. This is particularly so if such persons are wearing parachute harness or lifevests. Once in the raft, all personnel should seat themselves on the floor and remain in that position if at all possible. Movement within the raft should be restricted as much as possible to keep friction at a minimum. All sharp objects should be collected and stored, especially jeweled rings, wrist watches, etc. All loose articles of equipment should be properly packaged to protect the raft fabric.

LR-1 LIFERAFT ASSEMBLY

The LR-1 is a one man raft. The methods of rigging the raft to the various types of parachutes have been discussed in other chapters of this training manual. The configuration of a packaged LR-1 liferaft assembly, complete with accessories and survival items, will vary according to application. The survival items required must be packed in either the combination

PR.355

Figure 15-18.—Boarding the LR-1.

carrying case and equipment container, or in the equipment container, as applicable. The remaining space in the container may be used for specialized equipment deemed necessary for specific environmental or geographic conditions as directed by the Area Operating Commander.

The four basic packaged LR-1 liferaft assemblies include the standard soft pack, helicopter back pack, high speed soft pack, and the rigid seat survival kit.

For specific aircraft applications of the LR-1 liferaft assemblies refer to NavAir 13-1-6.1.

This section will describe the components of the LR-1, the survival equipment, and the procedures for performing inspections and maintenance. Procedures which parallel those already outlined for multiplace rafts are not repeated.

FLOTATION TUBE

The body of the liferaft consists of an encircling buoyant tube. The flotation tube is made in one continuous chamber from type N fabric. There are no internal bulkheads as in the multiplace rafts. Various attachments and configuration of the flotation tube are shown in figure 15-20.

SEAMS

All laps used in the seam construction of the flotation tube are five-eights inch wide, covered inside and out with type R tape, three-fourths inch wide.

CYLINDER CARRIER

Figure 15-20 shows the location of the cylinder carrier on the flotation tube. The cylinder carrier is 2 inches in diameter.

ORAL INFLATION TUBE

The valve on the oral inflation tube closes automatically by spring pressure when it is not held open. The valve is locked shut by turning the mouthpiece in a clockwise direction. The 3/8-inch oral inflation tube is cemented to the valve at one end, and at the other it is equipped with a molded flange which is cemented to the flotation tube.

11190

Figure 16-27.—System performance versus maximum range.

the radar set. (It should be noted that tuning the frequency meter to resonance will cause a dip in the power meter reading.)

The desired output signal is obtained by setting the test set function selector switch to the position that provides the desired waveform to the klystron oscillator reflector. Both the frequency and power of the klystron oscillator are controllable.

Before any measurements of receiver sensitivity can be made, the receiver must be accurately tuned to the radar-transmitter frequency. To measure the receiver frequency, the test set is connected to the radar set directional coupler. (Receiver frequency may be measured with the test antenna.) However to get accurate results, the sensitivity tests that usually follow frequency tests must be made using the directional coupler.

Tune the test set to the radar-transmitter frequency as described in the Operation Instruction Manual for the test set. Upon checking, if the receiver frequency is found to be different

PR. 356

Figure 15-19. —Righting a capsized raft.

PR. 357

Figure 15-20. —LR-1 liferaft assembly.

BOARDING STRAPS

Five handles or straps are provided as aids for boarding the raft.

INFLATION SYSTEM

The flotation tube is inflated with a CO_2 charge weighing 0.50 pound (+ 0.01 pound). The CO_2 cylinder is mounted in the cylinder carrier and the cylinder valve is threaded into the inlet check valve of the pararaft. The LR-1 life raft is inflated either manually by pulling the inflation assembly actuating lanyard, or automatically on LR-1 (RSSK) by gravity drop on kit actuation.

SEA ANCHOR

The sea anchor is tied to the pararaft mooring line with type III nylon line, using a bowline knot; the other end is tied to the sea anchor mooring patch with a square knot. The bitter ends of both knots are served with nylon thread to prevent them from untying. Before tying the knots, the ends of all nylon line are HEAT FUSED to prevent fraying.

Sea Anchor Pocket

The purpose of the sea anchor pocket is to prevent entanglement of survivors in the sea anchor line during boarding of the raft. Figure 15-21 shows the method of folding the sea anchor and line.

Downed aircrewmen should remove the sea anchor from the pocket and cast the anchor adrift immediately after entry into the raft.

SECURING LINE

The securing line is a 5-foot length of nylon cord. This line is used to secure the pararaft to its carrying case and equipment. The line is tied with a square knot to the pararaft sea anchor patch. The other end is also tied with a square knot through the grommet in the pararaft case. The free ends of the knots are bound or sewed with type B nylon thread.

WEBBING LANYARD

A nylon webbing lanyard 1 inch wide and 6 feet long is provided to secure the pararaft to the user. One end of the lanyard is equipped with a 1 1/8-inch snaphook. The other end is secured to the CO_2 cylinder neck by means of a loop formed at the end of the webbing, encircling the cylinder neck.

PR.358

Figure 15-21.—Method of folding the sea anchor and line.

MARKINGS

To modify the stenciled markings on the LR-1, compare the markings on the raft with NavAir 13-1-6.1. Use orange or black paint depending on the affected surfaces.

EQUIPMENT

The following equipment is considered essential and must be provided in the LR-1 liferaft: Two Mk-13 Mod 0 day and night distress signals, 2 dye markers, a signal mirror, rations, desalter kit, water storage bag, nylon cord (50 ft), bailing sponge, shark repellent, sunburn ointment, GND/AIR emergency code card, and a survival radio.

The type of survival radio used will be directed by the Fleet Commander.

In order to prevent loss of equipment carried in the equipment container, each item must be suitably attached to a common nylon cord, conforming to type 1, MIL-C-5040. One end of the cord must be fastened to the equipment container.

11192

INSPECTION

Pararafts are inspected at the following times:

1. Prior to being placed in service.
2. With the aircraft inspection cycles up to and including 22 weeks as stipulated in NavAir 13-1-6.1.
3. Every 6 months in storage.

Pararaft kits that are rigged to seat type parachutes require a closer inspection than those rigged to the chest type because of the weight imposed upon them. The individual's weight causes trouble in the form of chafed and badly damaged materials, bent objects, and an overall impacted condition. Every time parachutes containing pararaft kits are repacked, the equipment should be rearranged and inspected closely, keeping weight factors in mind.

In addition to the trouble caused by the applied weight, another consideration is also important. This concerns flatness and smoothness of the entire assembly. An improperly packed pararaft causes discomfort and fatigue to those who sit on it, even though they are separated by a cusion containing a metal pan.

When pararafts are being used every day, inspect the condition of each pararaft where the cylinder is liable to chafe the raft fabric. Chafing gear sometimes shifts or is worn through when subjected to hard usage. Also examine the inlet valve, where it joins the tube, for cracks or signs of breaking away. This inspection does not require the removal of the raft from its case, only the opening of the front section of the case.

The procedure for inspecting and testing the pararaft are the same as those given for the multiplace rafts (refer to NavAir 13-1-6.1). Where there are considerable differences in their construction, certain steps may be eliminated or added as necessary. For example, pararafts are not constructed with internal bulkheads. Since there is only one continuous flotation tube, the internal bulkhead test is not necessary on the pararaft. The pararaft is fitted with an oral inflation tube, but it serves the same purpose as the topping-off valves on the multiplace rafts. Therefore, the same general considerations given the topping-off valves should be applied to the oral inflation tube. Although the exposed end of the oral inflation tube has no rough edges, it is kept in a supporting pocket.

PACKING

Prior to commencing the packing procedure, make certain that the pararaft is completely deflated. Careless or improper deflation of inflatable equipment will result in expansion at high altitudes, causing severe discomfort or danger to personnel and aircraft. Higher altitudes cause progressively greater expansion. Entrapped air which merely causes discomfort at 25,000 feet may pin a pilot in his cockpit at higher altitudes. Deflation may be adequately accomplished by use of a suction pump such as an ordinary household vacuum cleaner.

Figure 15-22 illustrates the sequence of steps in packing the LR-1 raft. Each item in the equipment side of case should be secured in train to prevent loss. The looped end of the webbing lanyard, attached to the cylinder neck, must not interfere with the action of the valve pull. The valve pull-toggle must be placed in an accessible position. After the packing is completed, the packer must sign the packing card enclosed in the pararaft case.

MAINTENANCE

Repair and cleaning of the LR-1 raft is the same as that given for multiplace rafts except that for patching purposes, type N fabric is used with the lightweight fabric of the pararaft. Flotation tube seams and seams joining the tube to the bottom of the pararaft are not to be repaired.

LR-1 LIFERAFT HIGH-SPEED CONTAINER

Parachutes which utilize the high-speed container are the NB-5 and NB-7 integrated harness and parachute assembly.

To prevent the loss of the raft and equipment container on bailout or ditching, a 4-foot length of 550-pound nylon line should be used. Tie one end of the line to the slide fastener handle of the equipment container and the other end to the 1/2-inch nylon tape loop located inside the high speed container, using a bowline knot at each end. Insert the equipment container with the slide fastener inboard in the high speed container assembly. Tie a second piece of 550-pound nylon line 4 feet in length to the bow of the LR-1 raft and secure the other end to the 1/2-inch loop located inside the high speed container, using a bowline knot at each end.

11193

PR.359

Figure 15-22.—Sequence of steps in packing the LR-1 liferaft.

Lay the raft out for repack, exposing the CO_2 bottle. Make certain the raft is completely deflated. Figure 15-23 illustrates the sequence of steps for packing the LR-1 liferaft in the high-speed container. After the raft is completely rolled, insert the raft in the container with the ripcord assembly and handle in proper position as shown in figure 15-24. Complete the insertion of the raft in the container. Close the container using temporary locking pins. Install the ripcord assembly as shown in figure 15-25 and safety-tie the ripcord locking pin with type I or II size A thread. Close the protective coverflap using the slide fastener.

11194

PR.360

Figure 15-23.—Sequence of steps for packing the LR-1 in the high-speed container.

Safety-tie the ripcord handle in the high-speed container pocket with one turn of type I or II size A or E thread, through the pocket and around the ripcord handle as shown in figure 15-26.

LR-1 LIFERAFT LANYARD

The liferaft lanyard is easily located and identified by its distinctive bulk. The bulk of the lanyard aids the aircrewman in maintaining a positive grip on the lanyard during its transfer from the high-speed LR-1 container to the attachment point on his personal equipment.

The overall length of the lanyard must not be less than 4 1/2 feet. NavAir 13-1-6.1 contains instructions for modifying the LR-1 raft lanyard in the high-speed container.

CHAPTER 16

RECHARGING CARBON DIOXIDE CYLINDERS

Carbon dioxide is a component of the atmosphere. It is formed in the process of respiration, in combustion of all carbonaceous material, and in fermentation.

CO_2 (the chemical symbol for carbon dioxide) is a colorless gas, possessing a faint pungent odor and a slightly acid taste. It does not burn and does not ordinarily support combustion. However, metals such as magnesium, when ignited, will continue to burn in it while giving off oxides and liberating carbon. CO_2 gas is 1.53 times heavier than air and requires only a pressure of 600 psi below a temperature of 88° F to liquefy. It can be condensed into a colorless liquid and stored in this state under pressure in cylinders. When the cylinder valve is opened, gaseous CO_2 escapes and, because of the rapid drop in pressure and temperature, forms carbon dioxide snow. This snow, when compressed into blocks or cubes, is what we know as dry ice. Dry ice, in solid form and at atmospheric pressure (14.7 psi), evaporates, remaining at -110° F until it disappears. It is excellent for specialized refrigeration.

There are many natural carbon dioxide wells in the earth's surface. Yellowstone National Park has several of these wells. In some caves the CO_2 is so dense that animals are suffocated when they wander into them. Since CO_2, in addition to being heavier than air, is both invisible and practically odorless, it presents a particular hazard. As in caves, it tends to collect in low, unventilated places, such as below decks aboard ship. Men encountering these conditions run the risk of smothering to death. Small percentages of carbon dioxide will cause tiredness and perhaps headaches. Experiments have shown that a 3 percent concentration of CO_2 in the air will double the breathing effort, 5 percent will cause panting, 8 percent will cause marked distress, and 10 percent will cause unconsciousness very quickly.

Treatment of exposed personnel includes removal from the CO_2 laden atmosphere, artificial resuscitation, administering oxygen, and keeping the patient warm.

The PR's association will carbon dioxide is mainly in the recharging of cylinders used in the inflation of liferafts and those used in aircraft fire extinguishing systems. The servicing of the CO_2 firefighting equipment commonly used at shore establishments and aboard ship is not a part of the PR's duties.

Carbon dioxide is ordinarily procured from local commercial sources. In some locations the Navy manufactures its own. CO_2 is purchased or accounted for by the pound, since it is measured in a liquid state. Gas (CO_2 not in a liquid state) is measured on a volume basis and purchased by the cubic foot.

Standard supply cylinders are designed to contain 50 pounds of carbon dioxide and are procured through normal supply procedures. As an example, an order for 300 pounds of CO_2 would indicate a request for 6 supply cylinders.

CO_2 RECHARGE EQUIPMENT

Carbon dioxide recharge equipment is manufactured for the Navy by several different companies. The two most widely used units are those manufactured by the C-O-TWO Company of Newark, New Jersey, and the Walter Kidde Company of Belleville, New Jersey.

A typical C-O-TWO recharge unit is shown in figure 16-1 and consists of a supply cylinder containing 50 pounds of CO_2, a tilting rack for inverting the supply cylinder, a motor-driven pump, a rack for inverting the cylinder being recharged, a scale for determining the weight of the cylinder being recharged, and the necessary high-pressure hoses, control valves, adapters, etc., to properly hook up the equipment.

11198
CCIII

PR.39

Figure 16-1.—C-O-TWO recharge or transfer unit.

Before learning the operation of any specific type of recharge equipment, the PR should be familiar with the following general information, which applies to all units.

Carbon dioxide recharge equipment will pump CO_2 in its liquid state only, and the amount of liquid CO_2 a cylinder contains will vary with the temperature and pressure. For example, a standard 50-pound supply cylinder contains approximately 38 pounds of liquid CO_2 and 12 pounds of gaseous CO_2 at a temperature of 70° F. It follows, then, that the cooler the supply cylinder and cylinder being recharged, the more efficient the operation of the transfer equipment. For this same reason, the time required to recharge an empty cylinder increases with the temperature of the cylinders.

When recharging a cylinder, it will remain cooler and may be filled faster if inverted, rather than left in an upright position. Large cylinders, which are impractical to invert, may be placed in a horizontal position for charging.

Standard commercial supply cylinders in 50-pound sizes are obtained with or without a syphon tube. When transferring from a cylinder without a syphon tube, the cylinder must be inverted. Supply cylinders with syphon tubes should be maintained in an upright position, not more than 60 degrees from vertical.

After all the liquid CO_2 has been transferred from a supply cylinder (approximately 80 percent of net contents), the efficient transfer of CO_2 will cease. Then, a new fully charged supply cylinder must be used to finish charging a cylinder to its fully rated capacity. The major part of the CO_2 remaining in the supply cylinder can be used when recharging another empty cylinder, as the CO_2 gas will transfer itself under its own pressure until the pressure in both cylinders is equal. In this manner, the most economical use of the supply cylinder contents is made.

C-O-TWO TRANSFER UNIT

The general procedure for operating the C-O-TWO unit shown in figure 16-1 is described in the following paragraphs. For more complete details on erection, operation, and maintenance of the unit, refer to Operation and Maintenance C-O-TWO Transfer Unit, NA 19-1-516.

General Operating Instructions

1. Connect the pump inlet hose to the supply cylinder outlet.
2. Connect the pump outlet hose to the recharging adapter on the cylinder to be recharged. The pump outlet valve is fitted with a shutoff valve.
3. Check all connections and make certain that they are properly and securely made up. This is very important. When making up connections, use a 12-inch wrench with a slow, steady pull. Do not jerk or hit the wrench with a hammer.
4. Make certain that the shutoff valve in the pump outlet hose is in the tightly closed position, and that the valve of the cylinder being recharged is open. Open the valve fully and back off 1/4 turn to prevent freezing the valve in the full opened position.
5. Fully open the valve of the supply cylinder.
6. Place the empty cylinder on the scale.
7. Carefully determine the net capacity and the total weight of the cylinder to be recharged and set the scale to equal the fully charged

11198

weight shown either on the side of the cylinder valve, on the cylinder, or on the nameplate band.

8. Open the shutoff valve in the pump outlet hose and allow the CO_2 in the supply cylinder to transfer to the cylinder being recharged under its own pressure.

9. After the CO_2 has stopped flowing into the cylinder being recharged under its own pressure (the weight of the cylinder being recharged will stop increasing), start the transfer unit and watch the scale carefully.

10. When the full capacity of the cylinder being recharged has been reached, perform the following operations in rapid succession:

a. Stop the transfer unit motor.

b. Tightly close the shutoff valve in the pump outlet hose.

c. Close the valve of the cylinder being recharged.

CAUTION: Do not close the cylinder valve or the shutoff valve while the transfer unit is pumping.

11. Disconnect the hose from the cylinder being recharged. Do this very slowly so as to allow the pressure trapped between the shutoff valve and the cylinder being recharged to escape. Remove the adapter.

12. Weigh the recharged cylinder carefully.

13. After recharging is complete, close the supply cylinder valve tightly and open the shutoff valve in the pump outlet hose very slowly, allowing all the gas in the pump to discharge to atmosphere.

NOTE: This transfer unit is to be used for carbon dioxide only. Do not use for oxygen or other gases.

WALTER KIDDE RECHARGE UNIT

Another widely used CO_2 recharge outfit is the Walter Kidde (fig. 16-2). This unit is supplied complete with the necessary adapters, valves, safety disks and bushings, nuts, bolts, and washers for making connections to the cylinder to be recharged; connections to the supply cylinder; and the tools for making minor adjustments to the unit. The motor is equipped with a safety switch.

The following operating instructions are general in nature. For detailed instructions on recharging specific types of cylinders, refer to Operation and Maintenance Kidde CO_2 Recharge Pump, NA 19-1-501.

General Operating Instructions

1. Connect strainer adapter to the supply cylinder outlet then make up coupling adapter nut (part No. 6071) securely. Make up coupling nut (18150) to the recharging adapter, using washer (6139) between these items. (See fig. 16-3.)

2. Be sure that the cylinder valve is open and ready for charging.

3. Place the cylinder to be recharged on the scale and note reading.

4. Open shutoff valve (24650) fully; make certain blowoff valve (24650) is fully closed. Start the recharge pump.

5. Open the supply cylinder valve fully, keeping constant check on the weight of the cylinder being recharged.

6. When the cylinder is charged with the proper weight of CO_2, stop the pump and close the shutoff valve securely.

7. Close the valve on the cylinder being recharged, then open blowoff valve.

8. Check the final weight of charged cylinder.

9. Close the supply cylinder valve securely. Relieve the pressure in the recharging pump and connections by opening the shutoff valve.

CO_2 SUPPLY CYLINDERS

Figure 16-4 illustrates the standard supply cylinder used universally in recharging various types of CO_2 cylinders. A cutaway view of the cylinder valve is also shown. Table 16-1 lists some of the most pertinent data concerning supply cylinders.

Cylinder Valves

Navy standard valves are of two basic designs: Packed valves and diaphragm type packless valves. CO_2 handwheel type valves employ the packless design.

Packed valves require a packing material around the valve stem to prevent leakage, whereas valves (used mainly in high-pressure cylinders) are sealed against leakage around the valve stem by flexible metallic diaphragms securely clamped to the valve bonnets.

The basic packless design may be classified into two types: (1) the NON-BACK-SEATING type, which is designed so that the metallic sealing diaphragms may NOT be replaced

11200

than the previously measured transmitter frequency, the radar-receiver local oscillator is improperly adjusted or the transmitter frequency may have drifted.

There are two basic methods of measuring receiver sensitivity. One method is the pulse method where a pulse of measured amplitude and width is generated and coupled to the radar receiver. This method is rather difficult as consistent results require that the signal generator be tuned very accurately to the receiver frequency.

The second method employs a FM generator to sweep the signal generator across the receiver frequency. This method insures that the test signal is within the passband of the receiver. It also offers two main advantages over the pulse method; tuning the test set to the receiver frequency is not as critical, and receiver bandwidth tests can be made with relatively few changes in test set adjustments after sensitivity tests have been made.

Receiver bandwidth is defined as the frequency spread between the half-power points on the receiver response curve. Receiver bandwidth is specified for each radar, but wide variations are tolerated. If either the bandwidth or the shape of the receiver response curve is not within tolerances, a detailed check of circuit components may be necessary. Remember that a considerable change in the value of circuit components is required to alter the response materially. It is suggested that the receiver response be checked after any extensive repair to an IF amplifier.

Figure 16-28 shows a typical response curve of a radar receiver. The half-power points are shown as 3-db below maximum (midfrequency) response. Since the curve is plotted in terms of voltage, these points are also represented by the 70.7 percent voltage points ($\sqrt{1/2} = .707$) as shown in figure 16-28.

Figure 16-28.—Receiver response curve.

The time required to permit TR recovery is determined by the time it takes the TR switch to deionize after each transmitter pulse. It is usually defined as the time required for the receiver to return to within 6-db of normal sensitivity after the end of the transmitter pulse. However, some manufacturers use the time required for the sensitivity to return to within 3-db of normal or to full sensitivity. TR recovery time is the factor that limits the minimum range of a radar because the radar receiver is unable to receive signals until the TR switch is deionized. In various radar sets, the recovery time may vary from about 3 to 20 microseconds.

The primary function of the TR section is to protect the crystal detector from the powerful transmitter pulse. Even the best TR switches allow some power to leak through; but when the switch is functioning properly, the leakage power is so small that it does not damage the crystal. It has been found, however, that the useful life of a TR tube is limited because the amount of leakage and the recovery time increases with use.

To insure efficient performance, some technicians make it a policy to replace the tube after a given number of hours of use. A better practice is to measure the TR recovery time at frequent intervals and make a graph or chart, which will immediately disclose any change in performance. Figure 16-29 shows how the recovery time is correlated with leakage power. Note that the end of the useful life of the TR tube is indicated by an increase in recovery time.

This method of checking the condition of a TR tube is reliable, because the recovery time increases before the leakage power becomes excessive. In practice, the TR tube is replaced when any sharp increase in recovery time becomes apparent. Ambient temperature has an effect on recovery time. The colder a TR tube, the greater is its recovery time. When tests are conducted under widely varying temperature conditions, this effect must be considered.

One method used in testing a TR tube is to measure the keep-alive current. This current maintains the TR tubes partial ionization to make the firing more reliable, and thus helps protect the crystal. The current is usually

FOR BEST RESULTS KEEP SUPPLY CYLINDER COOL.
SEE RECHARGING INSTRUCTIONS.

PR.365

Figure 16-3.—Basic connections for Walter Kidde unit.

Diaphragms are fabricated from materials selected for service at high pressure while dynamically loaded. In addition, they are often of a design suitable only for use with valves fabricated by a given manufacturer and for a specific gas.

One of the features of the Navy gas valve program (also civilian agencies) is to provide noninterchangeable valve outlets and connections for different gases to prevent using the wrong gas at any time.

Leaking Valves

Cylinders with leaking or defective valves must be turned in to supply for overhaul. This is especially true in the case of stripped threads or bent stems.

Leakage is sometimes caused by the presence of dirt or other foreign particles in the valve or on the valve seat. This type leakage may sometimes be corrected by partially opening and then closing the valve to blow out the material. If

11202

Outlet connection	3/4 inch

*Temperature of 68° - 70° F and atmospheric pressure.

leakage continues, the cylinder should be removed to a safe place in the open, if possible, and emptied by opening the valve.

SAFETY DEVICES

Safety devices for CO_2 cylinder valves consist of an unbacked safety cap with a rupture disk. It consists essentially of a safety cap covering a safety port in the valve. The cap retains a frangible disk firmly over the safety port. Under excessive pressures ranging from 2,700 to 3,000 psi, the safety disk ruptures and allows the gas in the cylinder to vent to atmosphere.

LIFERAFT INFLATION EQUIPMENT

Figures 16-5 through 16-11 illustrate various types of liferaft inflation equipment items. These items consist of various sizes of cylinders and discharge heads and valves.

PR.368

Figure 16-6.—Cylinder and valve assemblies used on the pararaft.

DISCHARGE HEADS

Two types of discharge heads are commonly used. These are the cutter type and the seat type. A description of the operating principles of each type follows.

Cutter Type

Pulling a cable releases the cutter which is under spring action. The cutter pierces a sealing disc in the neck of the cylinder. CO_2 discharges through the ruptured disk, bypassing the cutter and passes on through the outlet into the raft inflation compartment. A new disk must be installed in the cylinder adapter after each use. This necessitates the temporary removal of the head or bonnet during the recharging process.

Seat Type

Pulling a cable turns a cam or sheave which actuates a stem and opens a seat, thereby admitting CO_2 into the raft compartment through the outlet of the discharge head. It is not necessary to remove the discharge head for recharging after each use. A disk is not employed.

CYLINDERS

The cylinders used in conjunction with emergency equipment, designed for use in aircraft, must be shatterproof. Shatterproof cylinders must be stenciled with the phrase "Non-Shatt" longitudinally 90 degrees from the titles. Letters must be black or white and approximately 1 inch in size. The shatterproofing is accomplished by either a heat-treating process, or by a wire wrapping which encompasses the body of the cylinder throughout most of its length. Non-shatterproof CO_2 cylinders, such as some older type supply cylinders, do not carry the distinguishing white stripe. Only shatterproof CO_2 cylinders should be used in aircraft systems and related equipment.

All liferaft cylinders are equipped with a syphon tube. The syphon tube may be the straight type or the flexible type, depending on how the cylinder is to be mounted. Figure 16-12 illustrates both types of syphon tubes.

Cylinders equipped with flexible syphon tubes are marked with a black stripe; those having a straight type are marked by a spot, as shown in figure 16-12.

PR.370

Figure 16-8.—Cylinder, disk body, and discharge head assemblies used on multiplace liferafts.

All CO_2 cylinders used in connection with aircraft fire extinguishing equipment (both portable and built-in types) must be serviced to operate throughout the temperature range of -65°F to +150° F. This is accomplished by the addition of 200 psi of dry, oil-free nitrogen to each cylinder and then adding the proper charge of carbon dioxide. Cylinders charged in this manner are referred to as winterized cylinders.

Cylinders which are to be winterized are identified by a yellow dot 3/4 inch in diameter, or larger, on opposite sides of the cylinder.

The addition of nitrogen in CO_2 cylinders provides additional pressure which expels the CO_2 at extremely low temperatures at a much higher rate than would the pressure of the CO_2 itself.

CYLINDER MAINTENANCE

Cleaning and Painting Cylinders

Cylinders should never be painted colors other than those indicated in the color code for compressed gas cylinders in Military Standard 101A. When camouflage is necessary, canvas or other materials painted with camouflage colors may be placed over the cylinders.

Cylinders should never be painted on their interior surfaces.

Valves must be kept free from paint. Navy and Interstate Commerce Commission serial numbers and test markings must not be obliterated.

Before painting cylinders, all loose paint, scale, rust, and dirt must be removed. When spark-producing tools, such as wire brushes or metallic scrapers are used, the cleaning operation should be done in the open or in a well ventilated compartment.

Before any cleaning operation, the valves, safety devices, and fusible plugs should be tested for leaks. Leaking cylinders should not be cleaned, but should be returned to an authorized repair activity.

Testing Cylinders

Interstate Commerce Commission regulations require quinquennial (5-year) retesting

11206

of all CO_2 cylinders. Cylinders for which prescribed retests have become due must not be recharged until retests have been properly made. Cylinders which have been charged prior to the expiration of their retest period may be shipped and used until empty before being retested.

The 5-year hydrostatic tests are performed by naval and civilian establishments under regulations of the Interstate Commerce Commission, and specially approved testing equipment is required. Since ships are not authorized to conduct such tests, empty cylinders with expired test periods should be returned to the nearest naval supply point or cylinder testing activity marked "for retest."

Repairs

Cylinders are repaired only by activities specifically authorized to perform such work. To assure that all cylinders aboard ship are in satisfactory and serviceable condition, periodic inspections should be made. Defective cylinders should be relieved of pressure and turned in to the nearest supply point in exchange for other cylinders.

The following marks or defects require a cylinder to be turned in for repair:

1. Severely dented, gouged, or corroded.
2. Bulges (deformation from internal pressure).
3. Damaged, split, or leaky seams.

Figure 16-29.—Graphic comparison of TR recovery time and leakage power.

about 100 microamperes, and falls off as the end of the TR tube life approaches. Another method is to measure the keep-alive voltage between the plate and ground of the TR tube when the voltage source is known to have the correct output, and to record this voltage for use as reference for future checks. However, these checks are not as reliable as a recovery time test.

TR recovery time can be tested by means of a setup that utilizes a signal generator of either the FM or the pulsed type.

RECEIVER TROUBLES

Poor system performance may be caused by low receiver sensitivity (high MDS), poor AFC operation, and poor minimum range.

Low Receiver Sensitivity

Low receiver sensitivity is evidenced by a high MDS test figure. The reasons for this condition may be either excessive noise generation or excessive signal loss preceding the IF amplifier section. As long as the noise present in the receiver output is excessive, the IF amplifier cannot contribute to the sensitivity. When defective or improperly adjusted, the following items may cause low receiver sensitivity; crystal mixer, local oscillator, IF amplifier (first two IF stages), and the TR and ATR tubes.

Crystals may be tested most effectively under actual operating conditions. However, a series of crystal testers, of which the AIL Model 390 is representative, is available, and one of these testers may be used to correlate the d-c characteristics with circuit performance. Important crystal characteristics are conversion loss, noise figure, IF impedance, and RF impedance. These characteristics may be correlated with front-to-back resistance ratio and back current at 1 volt.

Poor AFC Operation

Because proper operation of the AFC circuit is primarily dependent upon coupling between the AFC crystal mixer, the local oscillator, and the output of the magnetron, this portion of the circuit should be checked first. A variable coupling is usually provided to adjust the amount of local-oscillator signal injection to the AFC crystal mixer. Care should be taken to prevent overloading of the AFC crystal mixer, and reference should be made to the applicable instruction book as to the correct crystal current for proper operation. Usually one milliampere of crystal current is the allowable limit. If the degree of coupling is found to be correct, the trouble may lie in a defective local-oscillator tube. The local-oscillator must operate smoothly over the desired pull-in frequency range if normal AFC operation is to take place. In addition, it is essential to make sure that the local oscillator is operating in the correct mode. A magnetron with an improper frequency spectrum may also cause the AFC circuit to seem defective.

Poor Minimum-Range Performance

Minimum-range performance is controlled by the recovery time of the TR tube (and, if used, the pre-TR tube). Excessively long recovery time, of course, indicates the end of the useful life of a TR tube.

1118

CHAPTER 17

SAFETY BELTS AND SHOULDER HARNESSES

When wearing a safety harness, pilots can survive many crashes in which the cockpit or cabin remains reasonably intact, and the harness will also hold the pilot in the seat during ejection. The pilot is held in the seat while being ejected from the aircraft and then is automatically released from the seat after ejection.

What the harness must accomplish can be condensed into one statement: The lap belt and shoulder harness combination must be strong enough to hold a man in his seat under all reasonable stress conditions that might be experienced in high-speed flight, seat ejections, arrested landings, ditchings, or noseover crashes. It must be designed so that it can be released quickly.

Testing and inspecting of safety belts and shoulder harnesses are responsibilities of the PR.

PILOT'S LAP BELT AND SHOULDER HARNESS

Pilot's safety belts may be furnished as complete assemblies, consisting of lap and shoulder straps, or as individual components. There are several types of lap belts and shoulder harnesses. Figure 17-1 illustrates a complete assembly of one type.

PILOT'S LAP BELT (MS 22033)

Figure 17-2 illustrates the pilot's lap belt (MS 22033) showing its stitching pattern, parts assembly, and other significant physical characteristics. The MS 22033 lap belt assembly is subjected to periodic proof load testing to insure proper performance and integrity.

The proof load test for the lap belt amounts to 6,000 pounds doubled load or 3,000 pounds end load. After this test, no excessive deformation of the parts of stitching is permitted in the assembly. The latch must work freely when the load is released.

The ultimate load and proof requirements applied to a lap belt immediately after its manufacture (at the plant) should not be confused

with the periodic service tests given this equipment in the field. Field test proof loads do not even approach the tensile strength capacity of the assembled belt.

All major stitching is done with 6-cord nylon thread, size E being used in the less important tensile strength areas.

LAP BELT (AUTOMATIC-RELEASE TYPE)

Safety belts installed in aircraft with ejection seats in accordance with installation MS 16036 have an automatic-release feature incorporated. Its function is to hold the pilot in the seat during ejection, then open automatically and arm the parachute actuator after the pilot and seat are clear of the aircraft. This feature is designed to eliminate the necessity of the pilot releasing his safety belt at exactly the proper time and pulling his own ripcord, thus making ejection from an aircraft a much simpler and safer task.

The automatic-release type safety belt is cartridge operated. The complete assembly consists of the two belt halves, link latch, cable assembly, actuator assembly, and actuating unit assembly, as shown in figure 17-3.

When an automatic parachute actuator is used, the cable to the actuator is attached to the belt as shown in figure 17-3. When the belt is automatically separated and the pilot leaves the seat, the parachute actuator arming link is restrained by shoulders on the belt adapter link, pulling the cable and arming the actuator.

Piston action in the actuator assembly pulls the cable which is secured to a link holding the safety belt, shoulder harness and parachute arming wire together. If the automatic release fails to operate, the belt and shoulder harness can be released manually in the normal manner and the pilot must pull his own ripcord.

During normal use, the belt halves are manually joined and separated to attach or free the parachute actuator link so that the parachute

11212

PR.377

Figure 17-3.—Lap belt, automatic-release type.

can be removed from the seat without danger of actuating the automatic actuator.

A proof load test of 235 pounds is made when the automatic-release type safety belt is safetied with 0.040 copper lockwire. With no lockwire the proof load test is 175 pounds.

SHOULDER HARNESS

Figure 17-4 illustrates the H-type shoulder harness' dimensions, its stitching pattern, how it is put together, its parts, and other significant physical characteristics. The Y- and V-types are shown in figures 17-5 and 17-6. Where the lap belt remains fairly standard in its attachment to the pilot's seat, the shoulder harness must quite often be modified to fit its anchored location. This subject will be discussed under installation.

The anchor plate of the Y-type is adjustable, making it possible to lengthen or shorten the leg of the harness for a particular aircraft installation. The length of the leg of the Y must be adjusted so that there is adequate shoulder harness adjustment available, yet the crotch of the Y is not on the pilot's neck. During the manufacture and before acceptance, shoulder straps are subjected to a 3,500-pound ultimate load. A reasonable deformation of the parts is permissible.

A proof load of 3,000 pounds is also made and the straps must not have slipped appreciably through the adjustment loops. No noticeable deformation of any kind is permitted in this test. The proof test, then, establishes the highest tensile strength load a shoulder harness will withstand and still operate satisfactorily afterwards. The ultimate test is designed to stop at a tensile strength value just short of complete destruction. With reasonable care and by applying preventive measures, the shoulder harness will give long and honored service, easily passing its field test loads. The latest straps are made of Dacron, a "miracle fiber" similar to nylon. Dacron has less stretch than nylon.

NOTE: One assembly out of every 1,000 submitted for acceptance must be subjected to the ultimate load, and any safety belts or shoulder harness subjected to the ultimate load must not be shipped under contract.

All proof testing must be accomplished with all adjustable webbing components in the fully extended position.

Notation of compliance and date of proof load test must be recorded in the Aircraft Log Book, NavAir form 13090/4A.

MISCELLANEOUS SAFETY BELTS

CREWMAN'S BELT

The crewman's safety belt is designed to permit a reasonable amount of movement of the wearer in performing his duties while holding

11244

PR.379

Figure 17-5.—Pilot's shoulder harness—Y-type.

him securely in the aircraft. Figure 17-7 illustrates the MS 16070 belt. The tail strap which is adjustable (22 inches to 65 inches, approximately) can be anchored to any strong part of the aircraft's structure which is adaptable to its hook. Normally the smaller the amount of tail strap payed out, the less will be the danger of being whipped about when the aircraft is maneuvered violently.

As the crewman makes the attachment, he should anchor to a strong structural member making certain that the attachment will not mar or damage equipment.

GUNNER'S BELT

The gunner's belt side straps permit more movement than the pilot's type (which is designed primarily to hold him solidly in his seat). The length of the gunner's belt side straps is adjustable, thereby permitting the wearer security in standing as well as in sitting (See fig. 17-8.)

TROOP AND PASSENGER BELTS

Passenger belts are not used widely in naval aviation. They are installed in certain utility and transport aircraft and in some patrol types. The AN6506 troop belt is more generally specified for combatant type aircraft. Both types of belts have the quick-release feature. The troop belt is designed for an ultimate load of 5,000 pounds while the passenger type is designed to hold up under a load of 4,500 pounds. The webbing of troop and passenger belts is narrower than the pilot's belt, being approximately 2 inches. The AN6506 belt has the same type latching as the pilot's belt; however, the passenger type belt may vary with manufacturers. The AN6506 lap belt is given a proof load test of 2,500 pounds doubled load. All major stitching is accomplished with 3-cord nylon thread. Figure 17-9 shows the troop belt, while the passenger type belt and its application are shown in figure 17-10.

DAILY INSPECTION

Safety belts and shoulder harnesses are inspected daily for obvious signs of wear or deterioration of the metal parts and for wear or fraying of the webbing. Release buckles, snap-hooks, and other operating parts must be checked for proper functioning.

AIRCRAFT CALENDAR INSPECTION

Make a complete and thorough inspection of all equipment as for the daily inspection and include a close examination for corrosion, cracks, wear, fraying, rot, broken stitches or cuts in the webbing, cable or other parts.

Inspect all parts of the aircraft that the lap belts, shoulder harness, or inertia reel webbings may contact for any deformation such as

1. Anchor plate.
2. Adjuster.
3. Tab
4. Links (left and right).

PR. 380

Figure 17-6.—Pilot's shoulder harness—V-type.

sharp, jagged edges or roughness which may cause cutting or excessive abrasion.

Note the date of proof load testing of affected components. All components are to be proof load tested in accordance with Air Crew Systems Bulletin No. 2 to insure that the prescribed test intervals are not exceeded before the next calendar inspection.

Correct all discrepancies by local repair, modification, or by replacing components. If a discrepancy is found to be due to aircraft, seat, or restraint system design, submit a UR describing the defect in detail.

PAR/OVERHAUL INSPECTION

During aircraft PAR or overhaul, remove lap belts, shoulder harness and inertia reel, and takeup reel webbings. Conduct a thorough visual inspection as for aircraft calendar inspection. Perform proof load tests of all components and replace all cotton with nylon or dacron.

Test/Replacement Intervals

Lap belts, shoulder harness, and inertia reel webbings are to be proof load tested prior to installation and at intervals not to exceed the following:

Safety belts and straps which are made of cotton are removed from the aircraft, inspected thoroughly, and proof load tested every 6 months, then replaced with equipment made of nylon or dacron at the next PAR.

Safety belts and straps which are made of synthetic materials (nylon or dacron) are proof load tested during the applicable PAR cycle.

Proof Load Testing

Proof load testing is to be performed by intermediate maintenance activities and above. When components require proof load testing at other activities, they must be removed and sent to the nearest authorized activity with the capability to make the tests.

Test loads to be applied are listed in Air Crew System Bulletin No. 2.

Test equipment is to be recalibrated at intervals not to exceed 6 months.

When performing proof load tests, the load is to be applied by a loading device with a separation rate of approximately one inch per second, until the specified test load is reached. The load is to be held for 30 to 60 seconds and

11216

PR.381

Figure 17-7.—Crewman's safety belt.

11217

PR.382

Figure 17-8.—Gunner's safety belt.

then released. After completion of the test, inspect the item for broken stitches or other evidence of failure. There must be no perceptible slippage of the webbing through the adjustment loops, and the lap belt release must work freely. The quick release buckle of the lap belt must be operable under a pull of NOT OVER 45 POUNDS ON THE LATCH WHILE THE BELT IS SUBJECTED TO A STATIC LOAD OF 400 POUNDS.

BELT TESTING EQUIPMENT

Any one of several methods may be used for applying the prescribed proof load to the belts and straps; for example, mechanical tension tester, tripod lifts, deadweight loading, and others. The accuracy of the actual reading is more important than the manner in which the test load is applied.

A testing jig made from salvaged material is shown in figure 17-11. Its capacity is approximately 5,000 psi, a necessary reserve in power. The device can be mounted horizontally or vertically depending on the dictates of the physical plant. The movable head and the stationary head should be mounted far enough apart so that all lengths of belts and harnesses together with their necessary mounting clamps or adapters can be accommodated. In many cases, these have to be manufactured locally. Any PR can design the special jig necessary to do the job. For example, the part used in the aircraft to hold the mounting plate of a shoulder harness can be rigged to a testing jig and be used for the same purpose during test.

PR.383

Figure 17-9.—Troop type safety belt.

11218

PR.384

Figure 17-10.—Passenger type safety belt.

The device shown in figure 17-11 is adequate. Its construction details need not be followed closely. As a precaution, a wire cage must be constructed and placed over the area that lies between the two attachment heads. Then the operator will be guarded against the possibilities of sudden breakage and the accompanying whipping action that takes place.

Calibration

After construction of a testing device, it will be necessary to recalibrate the pressure gage from psi to pounds. This will insure an easily read value in relation to the specified tension load. Calibration can be done by any of the methods suggested below. The load in pounds (50-pound increments) can be marked directly on the gage dial, or a chart may be prepared to indicate the equivalent load in pounds for the corresponding psi graduations.

1. DEADLOAD. Secure the actuating cylinder in an upright position with the piston rod downward. Record the pressure (psi) required to lift deadloads of known weights.

2. SPRING. Place a large capacity spring scale of known accuracy between the two jaws of the test device and apply pressure. Record the loads in pounds shown on the scale versus the pressure in psi indicated by the gage.

3. DYNAMOMETER. Place a loop or Chatillon dynamometer of approximately 5,000 pounds capacity between the two jaws of the testing device and apply pressure. Record the load in pounds against the psi indicated by the gage.

Operation

The device requires only one man to operate it. Secure one end of the belt or shoulder strap to the ratchet rod and the other end to the piston rod. The length of the adjustable ratchet and the piston rod will afford sufficient clearance for testing belts of various lengths. Turn the selector valve handle to the loading position. Apply the required load by operating the hand pump. Read the load on the calibrated gage. Hold for 30 seconds or 1 minute, as specified for the particular harness, and release the load by turning the selector valve handle to an unloading position.

Recalibrate the gage every 6 months; breakages in the system should be repaired as they occur. Replenish the oil supply when needed.

Safety belts and shoulder harnesses found to be damaged or unable to withstand the strains of testing should be replaced with the latest equipment.

Figure 17-12 illustrates the application of a testing jig to a pilot's conventional lap belt. The belt support block shown in figure 17-12 is manufactured in accordance with Air Crew System Bulletin No. 2. The important thing to consider is its adaptability to the type belt or strap arrangement being tested. As long as an anchoring adapter does not produce any twists or undue strain on the article under test, it may be considered adequate.

11220

CHAPTER 17

RADAR INDICATORS

The video-frequency signal from the output of the radar receiver is fed to the indicator unit. The indicator unit consists of an indicator scope and the electronic circuits that are necessary to present the desired information on the scope. Only the methods of presenting the desired information on the radarscope and the external operating controls for the radar indicator scope will be discussed.

The type of scope used by most radars is similar to the type used in fast-sweep test oscilloscopes. The radarscope uses a rapid linear sweep with sweep time measured in microseconds.

All cathode-ray tubes (CRT's) have a few common elements. There is an electron gun, or cathode, that produces a beam of electrons. The face of the tube is covered on the inside surface with a phosphor coating that emits light when excited by the electron beam. The walls of the tube are coated with a conducting material that is kept at a high potential with respect to the cathode. This conducting material acts as an anode and collects the electrons after they have excited the phosphor coating on the face of the scope. Most CRT's have one or more grids, as well, to regulate the electron beam in direction and intensity.

METHODS OF DEFLECTION

The basic difference between CRT's lies in the method by which the electron beam is deflected, or moved, across the face of the tube. There are two widely used method of deflecting the electron beam. One is known as ELECTROSTATIC deflection and the other as ELECTROMAGNETIC deflection.

ELECTROSTATIC DEFLECTION

Most vacuum tubes have one common feature—a centralized cathode surrounded by various other elements. The electrons emitted from their cathodes are sent out radially in all directions. However, the electrons emitted from the cathode of a CRT are confined to a parallel beam by means of what is commonly called an electron gun.

The electron gun consists of a cathode, a grid which concentrates the electrons into a beam, and anodes which focus the beam of electrons on the screen.

The cathode of a CRT is indirectly heated and consists of a small metal thimble inside of which the heating element or filament is mounted. To make the cathode a good emitter when heated, the front end is concave and oxide coated as shown in figure 17-1. It should be noted that emission is from the front end only.

The filament, which is made of tungsten wire, is wound in a double spiral so that the electron beam will not be affected by the applied a. c. In this way the magnetic field of each winding is canceled by the equal and opposite field of the other winding. The filament is electrically insulated from the cathode. However, the insulation does touch the cathode to provide good heat conduction.

The grid is essentially a metallic cylinder in the form of a cap which surrounds the cathode and has a small hole in the end. The potential applied to the grid is negative in respect to the cathode and, as a result, an electrostatic field is developed between the two as shown in figure 17-2.

An electron that starts out in the direction of KA is bent by the lines of force so that it takes the path KCP. In a similar fashion, the electron which starts out in the direction KB is bent so that it takes the path KDP. Thus the paths of these two electrons intersect at P, and all the electrons which pass through the hole in the grid are concentrated in this manner into a beam of electrons.

The lines of force between the grid and cathode prevent the emitted electrons from diverging from the cathode and cause them to

CHAPTER 18

OXYGEN

No one can live unless he is able to get sufficient quantities of food, water, and oxygen. Of the three, oxygen is by far the most urgently needed. If necessary, a well-nourished man can go without food for many days or weeks, living on what is stored in his body. The need for water is more immediate but still will not become critical for several days. The stock of oxygen in the body is limited at best to a few minute's supply. When that supply is exhausted, death is prompt and inevitable.

Oxygen starvation affects a pilot or aircrewman in much the same way that if affects an aircraft engine. Both the man and the engine require oxygen for the burning of fuel. An engine design for low-altitude operation loses power and performs poorly at high altitudes. High-altitude operation demands a means of supplying air at higher pressure to give the engine enough oxygen for the combustion of its fuel. The supercharger or compressor performs this function.

The combustion of fuel in the human body is the source of energy for everything the aviator is required to do with his muscles and with his eyes and brain. As the aircraft climbs, the amount of oxygen per unit of volume of air decreases and the aviator's oxygen intake, therefore, is reduced. Unless he breathes additional oxygen, his eyes, his brain, and his muscles begin to fail him. He is designed for low-altitude operation and will not give satisfactory performance unless he is supplied the full amount of oxygen that his body requires. Like the engine, the body requires a means of having this oxygen supplied to it in greater amounts or under greater pressure. This need is satisfied by use of supplemental oxygen supplied directly to the respiratory system through an oxygen mask, by pressurizing the aircraft to a pressure equivalent to that at safe breathing altitudes, or both.

For purposes of illustration, an aviator's lungs may be compared with a bottle of air. If an open bottle is placed in an aircraft at sea level, air will escape from it continuously as the aircraft ascends. The air pressure at 18,000 feet is only half that at sea level; therefore, at 18,000 feet the bottle will be subjected to only half the atmospheric pressure it was subjected to at sea level. For this reason, it will contain only half the oxygen molecules it had when on the ground.

In like fashion, an aviator's lungs contain less and less air as he ascends and correspondingly less oxygen. Thus, the use of supplemental oxygen is an absolute necessity on high-altitude flights.

Above 35,000 feet, normal activity is possible up to about 43,000 feet by use of positive pressure equipment. This equipment consists of a "supercharger" arrangement by which the oxygen is supplied to the mask under a pressure slightly higher than that of the surrounding atmosphere. Upon inhalation, the oxygen is forced into the lungs by the system pressure. Upon exhalation, the oxygen pressure is shut off automatically so that carbon dioxide can be expelled from the mask. Normal activity is possible to 50,000 feet with the use of a pressure breathing oxygen regulator. Above 50,000 feet, the only adequate provision for the safety of the aviator is pressurization of the entire body.

Up to about 35,000 feet, an aviator can keep a sufficient concentration of oxygen in his lungs to permit normal activity by use of demand oxygen equipment that supplies oxygen upon demand (inhalation). The oxygen received by the body on each inhalation is diluted with decreasing amounts of air up to about 30,000 feet. Above this altitude up to about 35,000 feet, this equipment provides 100 percent oxygen. At about 35,000 feet, inhalation alone will not provide enough oxygen with this equipment.

11222

GSSII

EFFECTS OF HYPOXIA

A decrease in the amount of oxygen per unit volume of air results in an insufficient amount of oxygen entering the bloodstream. The body reacts to this condition rapidly. This deficit in oxygen is called HYPOXIA. A complete lack of oxygen, which causes death, is called ANOXIA. If the body is returned to its normal oxygen supply, one may recover from hypoxia, but cannot recover from anoxia.

Many persons are not aware of the enormous increase in need for oxygen caused by an increase in physical activity. Strenuous calisthenics or a cross-country run results in deep and rapid breathing. Even so mild an exercise as getting up and walking around a room may double the air intake. In the case of the aviator, leaking of an oxygen mask which may go completely unnoticed while the wearer is at rest may lead to collapse and unconsciousness when he attempts to move about from one station to another in the aircraft. A walkaround (portable) oxygen bottle sufficient for 24 minutes of quiet breathing may be emptied by 17 minutes of use when the user is moving about the aircraft.

Men differ in their reactions to hunger, thirst, and other sensations. Even an individual's reactions vary from time to time under different circumstances. Illness, pain, fear, excessive heat or cold, and many other factors govern what the response will be in each particular case. The same thing is true of individual reactions to oxygen starvation. The effects of a certain degree of hypoxia on a given person cannot be accurately predicted. For instance, a person may be relatively resistant on one day, but highly susceptible the next.

It is difficult to detect hypoxia, because its victim is seldom able to judge how seriously he is affected, or often that he is affected at all. The unpleasant sensations experienced in suffocation are absent in the case of hypoxia. Blurring of vision, slight shortness of breath, a vague, weak feeling, and a little dizziness are the only warnings. Even these may be absent or so slight as to be unnoticeable.

While still conscious, the aviator may lose all sense of time and spend his last moments of consciousness in some apparently meaningless activity. In such a condition he is a menace to his crew as well as to himself. Since the aviator understands that it is the reduced air pressure at higher altitudes which determines the effect upon his body, he depends upon the altimeter rather than his sensations or judgment to tell him when he needs oxygen.

CHARACTERISTICS OF OXYGEN

Oxygen, in its natural state, is a colorless, odorless, and tasteless gas. Oxygen is considered to be the most important to life of all the elements. It forms about 21 percent of the atmosphere by volume and 23 percent by weight.

Of all the elements in the universe, oxygen is the most plentiful. It makes up nearly one-half of the earth's crust and approximately one-fifth of the air we breathe.

Oxygen combines with most of the other elements. The combining of an element with oxygen is called oxidation. Combustion is simply rapid oxidation. In almost all oxidations, heat is given off. In combustion, the heat is given off so rapidly it does not have time to be carried away; the temperature rises extremely high, and a flame appears.

Some examples of slow oxidation are the rusting of iron, drying of paints, and the changing of alcohol into vinegar. Even fuels in storage are slowly oxidized, the heat usually being carried away fast enough; however, when the heat cannot easily escape, the temperature may rise dangerously and a fire will break out. This is called spontaneous combustion.

Oxygen does not burn, but does support combustion. Nitrogen neither burns nor supports combustion. Therefore, combustible materials burn more readily and more vigorously in oxygen than in air, since air is composed of about 78 percent nitrogen by volume and only about 21 percent oxygen.

In addition to existing as a gas, oxygen can exist as a liquid and as a solid. Liquid oxygen is pale blue in color. It flows like water, and weights 9.54 pounds per gallon.

Liquid oxygen, commonly referred to as LOX, is normally obtained by a combined cooling and pressurization process. When the temperature of gaseous oxygen is lowered to -182 F under about 720 psi pressure, it will begin to form into a liquid. When the temperature is lowered to -297° F, it will remain a liquid under normal atmospheric pressure.

Once converted into a liquid, oxygen will remain in its liquid state as long as the temperature is maintained below -297° F. The liquid has an expansion ratio of 862 to 1, which means

11223

that one volume of liquid oxygen will expand 862 times when converted to a gas at atmospheric pressure. Thus, 1 liter of liquid oxygen produces 862 liters of gaseous oxygen.

Until a few years ago, all oxygen carried in naval aircraft was in the gaseous state. As flight durations increased, however, it was found that weight and space problems involved with carrying increasing amounts of gaseous oxygen were becoming intolerable. Liquid oxygen has proven the answer to these problems. In its liquid state, oxygen can be "packed" into containers small and light enough to be carried even in flighter type aircraft without weight and space penalty.

In the aircraft, oxygen in the liquid state is carried in a container called a converter. This is a double-walled, vacuum-insulated container similar to the common Thermos bottle. The converter is equipped with the necessary valves and tubing for vaporizing the liquid and warming the gas to cockpit temperatures prior to breathing.

TYPES OF OXYGEN

Aviator's breathing oxygen (MIL-O-27210C is supplied in two types (I and II). Type I is gaseous oxygen, and type II is liquid oxygen. Oxygen procured under this specification is required to be 99.5 percent pure. This water vapor content must not be more than 0.02 milligrams per liter when tested at 70° F and at sea level pressure. This is practically bone dry.

Technical oxygen, both gaseous and liquid, is procured under specification BB-0-925. The moisture content of technical oxygen is not as rigidly controlled as is breathing oxygen; therefore, the technical grade should never be used in aircraft oxygen systems.

The extremely low moisture content required of breathing oxygen is not to avoid physical injury to the body, but to insure proper operation of the oxygen system. Air containing a high percentage of moisture can be breathed indefinitely without any serious ill effects. The moisture affects the aircraft oxygen system in the small orifices and passages in the regulator. Freezing temperatures can clog the system with ice and prevent oxygen from reaching the user. Therefore, extreme precautions must be taken to safeguard against the hazards of water vapor in oxygen systems.

OXYGEN COMPONENT TEST STANDS

Aircrew Survival Equipmentmen are responsible for shop testing aircraft oxygen system components, including regulators, emergency oxygen systems, pressure suit controllers, and other items. The AME is responsible for checking system components in the aircraft; however, in case of a suspected malfunction and for periodic maintenance testing, the component is removed from the aircraft and brought to the oxygen shop where it is tested by the PR. This testing is accomplished with the use of various types of test equipment, some of which are discussed in this chapter.

Regulator test stands are designed for testing oxygen regulators for flow capacities, oxygen concentrations, pressure characteristics, and various leakage tests at different simulated altitudes. This chapter covers the OTS-565, the -566, and the 62-A-116-E1 test stands.

OTS-565 SERIES TEST STANDS

The OTS-565 is designed for testing oxygen regulators under simulated altitude conditions. By measuring the outlet suction or pressure for specified flows at given altitudes, as well as the ratio of air and oxygen delivered by the regulator, it is possible to determine whether or not the regulator performance conforms to service requirements.

Provisions are incorporated for making various leakage tasks and emergency flow tests on regulators. When properly modified, the OTS-565 can also be used for testing full pressure suit components.

The OTS-565 is equipped with Vol-O-Flo elements which are used to create the pressure drop necessary to actuate the fluid in the input/output manometers. Earlier types of test stands were equipped with glass wool canisters designed for the same purpose. The OTS-565 is also different in that the complete test stand is calibrated in inches of water instead of liters per minute (lpm).

Figures 18-1 and 18-2 illustrate the front and rear views of the equipment. The top cabinet consists of an altitude chamber, piping assemblies, control valves, input/output manometers, Vol-O-Flo elements, pressure-suction manometer, altimeter, and pressure gages. The lower cabinet contains a Gast vacuum pump directly coupled to a 1 hp motor. Figure 18-3 illustrates the pump and motor assembly.

Principles of Operation

The OTS-565 test stand is suitable for testing demand, diluter demand, pressure breathing diluter demand, or the miniature pressure breathing demand oxygen regulators having outlet pressures up to 20 inches of water. Flows are metered over the range of 0-150 lpm. Since the input/output manometers of the OTS-565 test stand are calibrated in linear inches of water, all liter-per-minute expressions or, measurements must be converted to indicated

11226

PR.389

Figure 18-3.—Front view of vacuum pump and motor assembly.

inches of water through the use of the calibration charts furnished with each test stand.

The Vol-O-Flo elements are designed to be as altitude independent as possible, but calibration charts showing various altitude lines are furnished for all altitudes and must be used to convert actual flows in liters per minute to indicate flows in inches of water. The input manometers indicate the amount of air flowing into the chamber to provide the required dilution, and the output manometers measure the amount of air-oxygen mixture flowing out of the regulator.

The outlet valves and vacuum source provide a flow demand on the oxygen regulator, which the regulator demand valve attempts to provide. The regulator outlet flow measured by the output manometer indicates whether or not the regulator is performing properly.

In a pressure breathing regulator, the pressure is provided by an aneroid element in the regulator. The pressure breathing characteristics can be determined by evacuating the altitude chamber to the desired altitude by the use of the bypass valve while the outlet valve is cracked to permit a small flow (5 to 10 lpm) through the regulator. (This small flow must be allowed to prevent overloading of the pressure-suction manometer.) The outlet valve is then adjusted for various rates of flow, and the

11227

amount of suction or pressure is obtained from the pressure-suction manometer.

In a diluter regulator, the flow passing through the regulator is not all oxygen, since ambient air is being drawn into the regulator from the chamber.

Altitude Chamber

An airtight chamber provides a space for simulating the various test altitudes. The chamber is sealed by a plate glass cover which rests in two brackets in front of the chamber, and is held in place by the vacuum created inside the chamber.

The altitude chamber has eight connections—a high-pressure oxygen inlet, an air inlet, two chamber pressure taps, a regulator outlet pressure tap, a bypass outlet, a regulator outlet, and an electrical connection.

Piping

The piping consists of two major assemblies—an air inlet assembly which permits air controlled by the air inlet valve to enter the altitude chamber, and a regulator outlet-bypass assembly which permits evacuation of the regulator outlet through an outlet valve, or evacuation of the chamber through a bypass valve. The air inlet hole, which is covered with a fine screen, should never be blocked nor should dirt or dust be permitted near it.

Control Valves

Three needle valves with a metal to metal seat are used. One, in the air inlet assembly, permits air to be bled into the altitude chamber either to maintain a chamber altitude when the regulator is removing air from the chamber through its diluter, or to permit bringing the chamber back to atmospheric pressure from a simulated altitude. The other two valves are in the outlet-bypass assembly. The outlet valve controls the flow of air-oxygen leaving the regulator. The bypass valve permits independent evacuation of the altitude chamber. The bypass valve and inlet/outlet valves are labeled B, A, and C, respectively, on the panel.

Pressure Reducer

The pressure reducer supplied with the OTS-565 test stand is designed to regulate supply pressures up to 3,000 psi. A low-pressure gage is incorporated with a cutoff valve for testing of regulators requiring oxygen of 0 to 200 psi.

The cutoff valve is connected at the tee where it joins the low-range (200 psi) gage line. (See fig. 18-4.) Low oxygen inputs can be accurately set on the low-pressure gage without any danger of overloading the gage. At approximately 200 psi, the relief (popoff and bleed) valve will dump excessive oxygen pressure. This relief valve can also be used to bleed the oxygen pressure in the lines after completion of the performance tests. The pressure set on the low-pressure gage (0-200) will also register on the high-pressure gage (0-3,000); but due to the extreme high-pressure range of the gage, the needle will barely move off the peg.

Figure 18-4 is a schematic diagram of the pressure reducer and the gage connections. When an adequate supply pressure is turned on, it will always register on the 0-4,000 psi cylinder pressure gage. Turning the pressure reducer handle clockwise supplies and increases the pressure delivered to the regulator and is registered on the high-pressure delivery gage. Extreme caution must be observed to assure that the low-pressure gage cutoff valve is closed when setting pressures in excess of the range (0-200 psi) of the low-pressure gage.

Input/Output Manometers

Two Vol-O-Flo manometers are used in the test stand. Each Vol-O-Flo manometer is connected to a Vol-O-Flo manometer element. The input manometer is in the air inlet line downstream from the air inlet valve. The output manometer is in the regulator outlet line upstream from the outlet valve. The two manometers are calibrated to indicate flows at simulated (chamber pressure) altitude. The manometers are of the linear type in which the pressure drop across the Vol-O-Flo element is directly proportional to the volumetric (ambient) flow. The manometers have a range of 0 to 12 inches of water and are inscribed in linear inches.

In addition to the two small manometers, there is one pressure-suction manometer. The pressure-suction manometer is calibrated from -4.0 to +20.0 inches of water. The pressure-suction manometer is designed to measure the pressure and suction required to be delivered by the regulator. Excessive pressure or suction to the manometer is equalized by operating the pressure-suction bypass valve.

ESSIT 11228

PR.390

Figure 18-4.—Schematic diagram of pressure reducer and pressure gages for OTS-565 test stand.

CALIBRATION CHARTS.—Three copies of the calibration charts are supplied with each test stand. For testing the various regulators, a table of test criteria can be set up. This table can be computed from the Vol-O-Flo element calibration charts and the performance requirements for the regulator, published in the Service Instruction Manual for the regulator to be tested.

By the use of the charts, the actual flows shown in the manual as liters per minute are converted to an indicated figure shown as inches of water. The setting made on the manometers will be affected by the density of the gas passing through the elements and by the temperature. Since oxygen is 11.5 percent heavier than air, a flow of oxygen or air/oxygen will indicate higher than the same flow of air only. The test stand is calibrated with air, hence the oxygen or air/oxygen flow must be converted on the oxygen conversion graph to add the percentage of oxygen in the mixture and correct the reading, giving a corrected indicated figure.

Once a table has been established for a particular regulator, the operator has no need to make any correction to the manometer setting, other than for temperature variation.

TEMPERATURE CONSIDERATIONS.—On the linear type Vol-O-Flo element, the reading for a given flow is dependent on the gas (air, oxygen, or mixture), altitude, pressure, and temperature. The Vol-O-Flo elements are calibrated at the factory at a specified temperature, usually 72° F. If the test stand is operated in the temperature range of 65° to 80° F temperature corrections may usually be disregarded.

If greater accuracy is required or if the test stand is used at temperatures outside this temperature range, a temperature correction may be applied as follows: Determine the temperature for which the test stand was calibrated. If the test stand was calibrated against a field standard calibrator, the temperature of calibration is that for which the field standard correction curves were made. For each degree Fahrenheit the test stand is operating above the calibration temperature, the reading will be 0.15 percent too high. For each degree Fahrenheit below the calibration temperature, the manometer reading will be 0.15 percent too low. These

11229

Figure 17-1. —Filament and cathode of a CRT.

bend inward along the axis of the electron gun. They may even cause the electrons to cross over and diverge on the opposite sides. The grid of the CRT also controls the number of electrons emitted by the cathode in a manner similar to the action of a grid in a conventional vacuum tube. Therefore, the grid of the CRT performs two functions—(1) it controls the emission of the cathode, and (2) it acts as a lens which concentrates the electrons into a beam.

The intensity of the spot on the fluorescent screen depends on the number of electrons in the beam. The number of these electrons, as stated previously, is controlled by the difference in voltage between the grid and cathode or grid bias. Most CRT's utilize a potentiometer to vary the bias, thus enabling the operator to control the brightness of the spot. This potentiometer may be known by several different names such as intensity, brilliance, or brightness control.

In addition to the grid and cathode, the electron gun also contains two anodes. The construction of the anodes is similar to that of that of the grid. The first anode, sometimes called the focusing anode, is closer to the grid and is positive by a few hundred volts in respect to the cathode. The second anode or accelerating anode is next in line and is at a much higher positive potential than the first anode.

As shown in the previous illustration, the electron beam is in focus at point P which is close to the grid. However, the beam must also be in focus when it strikes the screen. This is accomplished by the electrostatic field between the two anodes. (See fig. 17-3.)

An electron introduced into the field at point P would tend to follow one of the lines of force and hit the more positive anode. Because of the high voltage on the anodes, the electron travels at an extremely high velocity and does not remain in the field long enough to be pulled completely off its course. However, it is subjected to forces as it moves through the field. For example, an electron which is traveling from point P along the path PAB is curved toward the axis by the lines of force and thus takes the path PAC. In the center, the lines of force are nearly parallel to the axis and in the direction of point S. Therefore, the beam of electrons is accelerated in the direction of point S.

The point when the electron coverge may be shifted by varying the strength of the field between the two anodes. This is usually done by a potentiometer which varies the voltage on the first anode. This control is sometimes called the focus control.

The screen is made fluorescent by a coating of materials deposited on its inner surface. These materials, called phosphors, emit light when struck by a beam of rapidly moving electrons. The color and persistence of the light depend upon the composition of the particular phosphor used. Phosphors are designated by

Figure 17-2. —Electrostatic field between grid and cathode.

Figure 17-3. —Electrostatic field between the first and second anode.

1120

temperature corrections are in addition to and independent of corrections for altitude or gas mixture.

Inspection

The test stand should be inspected every 6 months as follows:

1. Inspect all rubber tubing connections. If they show signs of wear or cracking, replace them.
2. Check the rubber sealing gasket around the chamber and wash it with soap and water if necessary. Keep the chamber cover glass clean and free of chips.
3. Prior to operating the vacuum pump, insure that the oil reservoir has sufficient oil. Each time that oil is added the oil trap should be dumped and cleaned. The recommended oil is pure mineral oil without additives. The electric motor should be greased periodically with a good grade of motor grease.
4. The altimeter should be checked against a master altimeter or barometer to make certain it is within allowable limits.

System Leak Test

The system leak test is performed weekly. Cap off the oxygen inlet inside the chamber and secure the low pressure gage cutoff valve. With a supply cylinder, containing at least 1,800 psi of oxygen, hooked up to the system, open the supply cylinder valve. Adjust the pressure reducer to apply 500 psi to the system, then close the supply cylinder valve. The maximum allowable leakage is 50 psi in 30 minutes. Read from the oxygen cylinder pressure gage #2-17.

Chamber Leak Test

This test is also performed weekly. Cap the oxygen inlet, and evacuate the chamber to about 50,000 feet. Hold this altitude for 2 minutes and drop the altitude to 40,000 feet. Close the valves fingertight and time the rate of altitude loss for 5 minutes. The allowable loss must not be more than 100 feet per minute. Refer to NavAir 17-15BC-505 for procedures to follow for correcting excessive leakage.

Intercomparison Test

The intercomparison test is performed every two weeks and is done to determine whether the Vol-O-Flo elements are still in calibration. The test is performed at 5,000, 15,000, and 30,000 feet, using flows of 5, 50, and 85 liters per minute at each altitude. Convert the actual flows to indicated figures for both the output and input; the input actual flows must be within 1 liter or 2 percent, whichever is greater, of the output actual flow.

The test is performed by capping off the oxygen inlet and securing the oxygen supply cylinder. Open the outlet valve and ascend to altitude. Set the first flow to be pulled as the stand is ascending. Upon reaching the first test altitude, 5,000 feet, open the inlet valve to stabilize the altimeter. Take the reading from the input manometer. It must be within tolerance. Repeat steps for the other flows and altitudes. Readings not within tolerance require the Vol-O-Flo elements to be cleaned. Refer to the test stand manual for procedures.

NOTE: If at any time the suction side of the pressure suction manometer becomes overloaded, the intercomparison test must be performed prior to testing a regulator.

OTS-566 TEST STAND

The OTS-566 test stand is designed for testing diluter demand oxygen regulators under simulated altitude conditions. It was designed especially for use aboard ship, but can be used ashore as well. The OTS-566 incorporates pressure indicating gages instead of manometers; otherwise it is practically identical to the OTS-565. These gages require no fluid; thus the roll of the ship has no effect on the readings.

The test stand consists of an upper cabinet mounted on the lower pump stand. The upper cabinet contains the altitude chamber, control valves, flow measuring gages, pressure-suction gage, altimeter, and piping. The lower pump stand contains a Gast vacuum pump identical to the pump used with the OTS-565. Front and rear views of the stand are shown in figures 18-5 and 18-6.

Altitude Chamber

An airtight chamber, mounted from the rear of the test stand panel, provides a space within which the various test altitudes may be simulated. The chamber is sealed by a transparent cover plate, which rests on rollers, and can be clamped to the front of the chamber.

Gages

The gages are known as sensitive diaphragm type with the output and input having the same calibration, 0 to 12 inches of water, as the OTS-565 test stand. The gages can be adjusted by removing the plug on the face of the dial and turning the zero adjusting screw. The pressure suction gage is calibrated from -2 to +20 inches of water and also incorporates the emergency bypass valve.

PR. 392

Figure 18-6. —Rear view of the OTS-566 test stand.

11232

Pressure Reducers

The OTS-566 has two pressure reducers. The first one, known as the high range pressure reducer, reduces the cylinder pressure of 3,000 psi down to a range of 50 to 2,000 psi. The low range pressure reducer is used to adjust inlet pressures in the range of 0 to 150 psi.

Ballast Tanks

There are three ballast tanks located inside the uppermost rear of the case. They are independent of each other and each is connected to the high side of the Vol-O-Flo elements and the pressure suction gage. The purpose of the tanks is to eliminate fluctuation of gage readings due to the sensitivity of the diaphragm.

Control Valves

Three needle valves are used. One, in the air inlet assembly, permits air to be bled into the altitude chamber, either to maintain a chamber altitude when the regulator is removing air from the chamber through its diluter air valve, or to permit bringing the chamber back to atmospheric pressure from a simulated altitude. The other two valves are in the outlet-bypass assembly. The outlet valve controls the flow of air-oxygen leaving the regulator. The bypass valve permits independent evacuation of the altitude chamber.

Gast Vacuum Pumps

There are several types of vacuum pumps used to remove air from the altitude chambers of oxygen system test stands. The major difference in the various pumps is the pumping capacity.

CONSTRUCTION.—The rotary Gast pump is a precision product with only 0.0015- to 0.0065-inch total clearance at the ends and top of the rotor. The vanes take up their own wear and last from 5,000 to 25,000 hours of operation, depending upon the application. Remember that it is designed for pumping dry air. Protect it against the entrance of dirt and excessive moisture. Lubricate it regularly and properly, and years of trouble-free service will be received.

OXYGEN SYSTEM COMPONENTS TEST STAND 62-A-116-E1

The oxygen system component test stand is designed to test and evaluate the functions of miniature regulators, console type and seat mounted regulators, diluter demand regulators, full pressure suit controllers (both kit and suit mounted), full pressure suit helmets, emergency oxygen systems, and some liquid oxygen converter components.

The test stand consists of an oxygen pressure and vacuum system with valving and instrumentation necessary to measure, test, and evaluate the performance and operating characteristics of the components described at simulated altitudes up to 150,000 feet.

Operation

The oxygen system components test stand is capable of testing a variety of system components; therefore, test procedures for specific items are not given. The preliminary operations and adjustments of the stand which must be accomplished prior to testing any component are covered.

A detailed view of the components test stand is shown in figure 18-7 and table 18-1 gives the purpose and use of the controls and instruments shown.

ALTITUDE CONTROLLER.—The altitude controller (B, fig. 18-7) is adjusted to the desired altitude for the high-altitude chamber. (NOTE: 20 psi is applied with the pressure reducer (P) before operation of the altitude controller.) Energize the vacuum pump and adjust the controller set knob (29) to position the red indicator to the desired point on the controller altitude gage (31). The high-altitude chamber will then evacuate to this altitude (indicated by the blank indicator of the controller altitude gage).

NOTE: The controller altitude gage indication is an approximation. To obtain a specific altitude, check the indication given on the controller altitude gage against the ALTM high-range (12) or the low-range (13) indicators, after a 2-minute stabilizing period.

If the indication on indicator (12) or (13) is higher, the high-altitude chamber must be bled to the proper altitude using the chamber bleed valve (K). If lower, carefully adjust the Controller Set Knob until the correct indication is observed on indicator (12) or (13).

REGULATED HIGH PRESS. Gage.	10	Indicates the amount of regulated input supply pressure.	*
REGULATED LOW PRESS. Gage.	11	Indicates the amount of regulated low input supply pressure.	*
ALTM HIGH RANGE Indicator.	12	Measures altitude chamber pressure to indicate the altitude equivalent within a 30,000- to 150,000-foot range.	*
ALTM LOW RANGE Indicator.	13	Measures altitude chamber pressure, and, under some circumstances, suit simulator tank pressure at pressures equivalent to altitudes within a 10,000- to 40,000-foot range.	*
PUMP CONTROL Switch.	17	Energizes vacuum pump.	All tests requiring chamber altitude.
PRESS. SUCTION Manometer.	25	To obtain accurate pressure indications at low pressures.	*
O_2 INPUT PRESS. Gage.	27	Indicates amount of regulated low input supply pressure.	*
Controller Set Knob.	29	Sets altitude reference point on altitude controller.	All tests requiring evacuation of the high-altitude chamber.
Controller Supply Gage.	30	Indicates amount of pressure at altitude controller input.	All tests where altitude controller is utilized.
Controller Altitude.	31	Indicates approximate altitudes to which the high-altitude chamber can be evacuated.	All tests requiring evacuation of the high-altitude chamber
Controller Output Gage.	32	Indicates amount of pressure at controller output.	Same as item 30.

*The use of these items is dependent on the component test being performed.

11238

Preliminary Procedures

Assuming that the test stand has been set up properly and that all necessary accessories have been attached, proceed as follows:

Oxygen pressure tests:

1. Make sure that all test stand valves and the valve at the oxygen supply cylinder are closed.

2. Place the leakage selection valve (F) in the HIGH position.

3. Open momentarily, then close the valve at the oxygen supply cylinder.

4. Observe the supply pressure gage (9) for 2 minutes. Any drop in pressure indicates leakage and must be remedied before proceeding.

5. Open the oxygen supply cylinder valve, and open valve (W).

6. Observe the regulated high-pressure gage (10) and rotate the high-pressure regulator (Q) clockwise until a pressure of 2,000 psi is indicated. Close the cylinder valve. Observe the regulated low-pressure gage (11); pressure indicated should be below 200 psi.

7. Observe the regulated high-pressure gage (10) for 2 minutes; no pressure drop should be noted. Turn valve (W) off. Bleed pressure by opening (S), then turn high pressure regulator (Q) to vent. After pressure is bled, close valve (S).

8. Rotate the high-pressure regulator (Q) counterclock wise to vent the system.

9. Place the inlet pressure on-off valve (L) in the ON position and cap the oxygen input (18).

10. Observe the regulated low-pressure gage (11) and the oxygen input pressure gage (27). Slowly open the low-pressure regulator (N) until a pressure of 70 psi is indicated on the gages.

11. Place the inlet pressure on-off valve (L) in the OFF position and the leakage on-off valve (G) in the ON position. Observe the rotometer leakage flowmeter (8). No leakage should be indicated.

12. Place the leakage on-off valve (G) in the OFF position and the inlet pressure on-off valve (L) in the ON position.

13. Observe the regulated low-pressure gage (11) and slowly adjust the low-pressure regulator (N) until a pressure of 160 psi is indicated. Observe the oxygen input pressure gage (27). Pressure indicated should be below 150 psi. Turn valve (G) to the ON position and valve (L) to the OFF position. Observe leakage rotometer (8). There should be no allowable leakage. Turn selector valve (F) to the LOW position and observe leakage rotometer (7). There should be no allowable leakage.

14. Close the pressure regulator (N), close the valve at the oxygen supply cylinder, and remove the cap from the oxygen input port (18) to vent the system. If above procedure is used, (L) will be off.

15. Place the inlet pressure on-off valve (L) in the OFF position.

High altitude chamber leakage tests:

1. Set the pressure selector valve (D) in the HG position and the leakage on-off valve (G) and the inlet pressure on-off valve (L) in the OFF position. See that a 0- to 50,000-foot altimeter is installed in the altitude chamber and that the chamber door is open.

2. Open the oxygen supply cylinder valve and set a pressure of approximately 2,000 psi on the supply pressure gage (9).

3. Adjust the controller set knob (29) to position the red indicator of the ALT controller (B) at a point below zero on the controller altitude gage (31).

4. Observe the controller supply gage (30) and adjust the controller regulator (P) to an indicated pressure of 20 psi. The same pressure should be indicated on the controller output gage (32).

5. Depress the START button of the pump control switch (17).

6. Place the reference pressure selector valve (0) in the SUIT SIMULATOR position and (M) in the controller position. Rotate the flutter dampener valve (J) and the suit simulator reference shutoff valve (R) one turn counterclockwise.

7. Remove the air inlet plug from the input fitting in the high-altitude chamber and close the chamber door.

8. Adjust the controller set knob (29) until an altitude of 30,000 feet is indicated on the ALTM low-range indicator (13). The same altitude should be indicated on the ALTM high-range indicator (12). If the indicators (12) and (13) do not agree refer to the applicable calibration instructions in NavWeps 17-15BC-11 and adjust as necessary.

9. Adjust the controller set knob (29) until an altitude of 40,000 feet is indicated on the ALTM low-range indicator (13). The same altitude should be indicated on the ALTM high-range indicator (12).

10. Adjust the controller set knob (29) until an altitude of 52,000 feet is indicated on the ALTM high-range indicator (12), then adjust the

11239

the letter P followed by a number which indicates its persistency. The higher the number, the longer the persistency. These numbers fall between 1 and 31 but bear no relationship to the time an image will persist on a screen. However, most airborne radar indicators use CRT's with long persistency.

CRT screens vary in size, color, and persistency. The most common size CRT screen is approximately 5 inches in diameter. Manufacturers indicate the size by using the size in inches as the first digit in the tube's designation.

The electrons reaching the screen give up energy in producing luminescence. When this is accomplished, they must be removed or a large negative charge would develop on the screen. Thus, some method must be used to return the electrons to the power supply. Since the electrons striking the screen are traveling at a very high speed, they cause other electrons to be emitted (called secondary emission). The aquadag coating, which consists of a conductive material deposited on the flare of the CRT, is connected to a very high voltage (See fig. 17-4.) Many of the secondary emission electrons are atracted by this high potential. Thus, the electrons are returned to the power supply. The aquadag coating also serves as a shield for the electron beam.

The deflection plates are the final components necessary to complete the electrostatic CRT. There are two pairs of deflection plates which are set at right angles to each other, and the electron beam passes between all four of the plates. The plates are called vertical and horizontal deflection plates according to the direction in which they deflect the beam and not according to the manner in which they are mounted. Figure 17-4 illustrates the mounting of the deflection plates.

The amount of deflection caused by a set of deflection plates depends upon the velocity of the electron beam, the voltage applied between the plates, and the spacing of the plates. A measurement of this deflection is called deflection sensitivity. Deflection sensitivity is defined as the number of millimeters the spot on the screen will be deflected when one volt is applied to the deflection plates. Thus, a deflection sensitivity of 0.22/volt means that for each volt d.c. applied between the plates causes a deflection of 0.22 mm.

A more useful measurement of deflection is known as the deflection factor—measured in volts per millimeter or volts per inch. This factor indicates the voltage that must be applied between the plates to obtain a deflection of 1 mm or 1 inch. Tube manuals give the deflection factor in volts per inch.

ELECTROMAGNETIC DEFLECTION

The electron gun of the electromagnetic CRT is very similar to the electron gun found in the electrostatic type of CRT. However, there are some differences in the two types which are primarily in the method of focusing and deflecting the electron beam. As the name implies,

Figure 17-4. —Electrostatic CRT.

1121

controller set knob to reposition the red indicator at a point below zero on the controller altitude gage (31). Controller output gage (32) should indicate a pressure of 20 psi. Allow a 2-minute stabilization period.

11. When the 2-minute stabilization period has elapsed, observe the altimeter in the high-altitude chamber, and record the time required for the large hand of the altimeter to rotate counterclockwise (drop) one revolution (1,000 feet). NOTE: The allowable drop is 1,000 feet in 20 minutes.

12. Depress the STOP pushbutton on the pump control switch (17). Open the chamber bleed valve (K) to bleed the high-altitude chamber and close the valve at the oxygen supply cylinder. Close all test stand valves.

TESTING OXYGEN REGULATORS

Oxygen regulator testing is a responsibility of the PR. This chapter covers the testing procedures for the Bendix 29252-A-2 regulator and the new Navy standard pilot's miniature oxygen breathing regulator type 226-20004.

There are a number of various types of regulators used in the Navy today. The recommended testing procedures for these regulators can be found in their respective Overhaul Instructions Manuals. All regulators must be tested before they are installed in an aircraft. They are also tested any time they are disassembled for repair or adjustment and periodically at intervals specified in the appropriate manuals.

BENDIX 29252-A-2 OXYGEN REGULATOR

The Bendix 29252-A-2 regulator is one of the latest and most compact diluter demand pressure breathing automatic safety pressure regulators to be developed. It is also the first seat mounted regulator, and is used both in flight and in case of emergency. It is designed to be used with the A13-A oxygen mask. It is constructed so that with a normal inlet pressure of 70 psi, it will deliver diluted oxygen from sea level up to approximately 30,000 feet. One hundred percent oxygen is automatically delivered up to 50,000 feet, which is the service ceiling of the regulator. The regulator delivers automatic safety pressure, not in excess of 2 inches of water pressure, from sea level up to 35,000 feet. It delivers automatic pressure breathing from 35,000 feet to 50,000 feet, not to exceed 18 inches of water pressure.

All tests on the Bendix 29252-A-2 regulator are conducted with the regulator in the horizontal plane and the air dilution control knob down. The following tests are conducted on the oxygen regulator test stand, OTS-565. Figure 18-8 is a cutaway view of the Bendix 29252-A-2 regulator.

Overall Leakage Test

Place the diluter control knob on 100 percent and cap the outlet port. Apply 70 psi inlet pressure, then soap the mating surfaces of the inlet fittings and regulator body. There should be no evidence of leakage.

Relief Valve Test

Place the diluter control knob on normal and cap the inlet port. Apply 16 inches of water pressure at the outlet of the regulator. The maximum allowable leakage is 0.01 lpm. Apply 24 ±2 inches of water pressure. The relief valve must vent 40 lpm at a pressure no greater than 26 inches of water pressure. Decrease the pressure at the outlet to 15 inches of water pressure. There should be no evidence of leakage.

Safety Pressure Test

Mount the regulator in the test stand. Insure that the mask flow line is connected to the regulator outlet. Place the dilutor control knob on normal and apply 70 psi inlet pressure. Record the pressure-suction manometer reading on a performance sheet. Hold zero flow for 5 minutes and record the pressure-suction manometer reading on the performance sheet. The pressure-suction manometer reading must not exceed 2 inches of water pressure. Increase the inlet pressure to 90 psi and place the air dilution control knob on normal. Record the pressure of the suction manometer reading on the performance sheet for flows of 70 and 100 lpm at sea level and 34,000 feet. To ascend in altitude, open the outlet valve to indicate 10 lpm flow and control the ascent with the bypass valve. For flows of 100 lpm the pressure-suction manometer must not exceed 2 inches water pressure nor drop below -1 inch water

11240

pressure. Return to sea level, place the dilution control knob on 100 percent, and record the pressure of the pressure-suction manometer reading on the performance sheet for flows of 70 and 100 lpm at sea level, and 34,000 feet. Decrease the inlet pressure to 40 psi, maintain 34,000 feet altitude, and record the pressure-suction manometer reading for flows of 0 to 55 lpm at 34,000 feet and sea level. Repeat this procedure for flows of 0 to 100 lpm. The recorded pressure must not drop below -1 inch water pressure, nor exceed 2.0 inches of water pressure.

Aneroid Closure Test

Place the diluter control knob on normal and apply 90 psi inlet pressure. Place the glass on the altitude chamber and open the outlet valve to indicate 40 lpm. The altimeter will stop climbing when the air dilution aneroid has closed. The aneroid must close between 28,000 feet and 32,000 feet. Record the altimeter reading on the performance sheet.

Oxygen Ratio Test

Place the diluter control knob on normal and set the inlet pressure on 90 psi. Open the outlet valve and ascend to the first altitude on the performance sheet. Adjust the outlet valve for the required test flows. Adjust the inlet valve to maintain the correct test altitude. Record the input manometer reading on the worksheet for all flows on the oxygen ratio table. Repeat the above step for all test altitudes and flows on the oxygen ratio table.

NOTE: The bypass valve must be opened to climb above the aneroid closure altitude.

Check Valve Test

Place the diluter control knob on normal and set the inlet pressure to 40 psi. Ascend to test altitude (20,000 feet) and adjust the outlet valve for the required flow of 30 lpm. Adjust the inlet valve to maintain correct test altitude. Record the input manometer reading. Readjust the inlet pressure to 25 psi and adjust the outlet valve for required flow of 30 lpm. Adjust the inlet valve to maintain the correct test altitude. Record the input manometer reading on the worksheet.

Pressure Breathing Test

Place the diluter control knob on normal. Set the inlet pressure to 90 psi. Adjust the outlet valve to indicate 10 lpm. Open the bypass valve and ascend to the first test altitude on the worksheet. Record the pressure-suction manometer. The pressure-section manometer reading must fall between the minimum and maximum on the positive pressure table. Repeat the test for each altitude in the positive pressure table for the inlet pressure of 40 psi.

MINIATURE OXYGEN BREATHING REGULATOR 226-20004

The 226-20004 oxygen breathing regulator is mounted on the mask for use both in flight and bailout or emergency. The regulator integrates with the A13A oxygen breathing mask. The assembly weighs 2.3 ounces and is about 2 5/8 inches in length and 2 5/8 inches in width. It is designed so that with an inlet pressure of 40 to 90 psig it will deliver 100 percent oxygen automatically to the user between the altitudes of 0 and 50,000 feet. The regulator incorporates automatic safety pressure buildup to a maximum of 2 inches of water pressure below 35,000 feet and automatic pressure breathing for altitudes about 35,000 feet. Figure 18-9 shows a cutaway view of the 226-20004 oxygen breathing regulator.

Bench Testing the 226-20004 Regulator

Inspect the inlet port of the regulator for loose screws. Secure all loose screws and apply glyptol to screwheads so that the screws do not tend to loosen. The regulators must be subjected to the following tests every 60 days.

Overload Test

Cap the inlet of the regulator. Apply a pressure of 25 inches of water pressure to the outlet of the regulator for 2 minutes. The following test will indicate any failure.

Outward Leakage Test

Plug the inlet of the regulator and apply a pressure of 11 inches of water pressure to the outlet of the regulator. Leakage must not exceed 20 cc/minute.

11242

PR.56

Figure 18-9.—Cutaway view of the 226-20004 regulator.

Demand Valve Leakage Test

Apply a pressure of 70 psig to the inlet of the regulator. Maintain a static flow condition at sea level for 5 minutes. After 5 minutes the regulator outlet pressure must not have exceeded 2 inches of water pressure on the pressure-suction manometer, nor dropped below 0 inches of water pressure.

Automatic Safety Pressure Test

Set up the regulator, making sure that the regulator outlet and piezometer restrictor are 1 inch apart. Remove the rubber tube from the regulator outlet. Set the inlet pressure to 40 psig. Record the readings on the pressure suction manometer at flows of 0 and 70 lpm. Set the oxygen inlet pressure at 50 psig on the pressure gage located within the altitude chamber. Record the pressure indicated on the pressure-suction manometer for regulator outlet flows of 0, 10, and 100 ambient liters per minute at sea level, 10,000, 20,000 and 30,000 feet. Use valves A and B to regulate chamber ascent and descent respectively, and valve C as the regulator outlet flow control valve.

SASII 11243

Repeat the test with the oxygen inlet pressure set at 90 psig on the oxygen pressure gage located within the altitude chamber.

NOTE: The recorded pressures for the tests discussed in the preceding paragraph must not go negative nor exceed 2 inches of positive water pressure.

Automatic Positive Pressure Breathing Test

With the regulator still set up in the test stand, set the oxygen inlet pressure on the oxygen gage within the altitude chamber at 50 psig. With a flow of 10 liters per minute, vary the altitude from sea level to 43,000 feet. Record the altitude at which the automatic positive pressure breathing device cuts in. This point will be evident when the pressure-suction manometer reading increases above 2 inches of water pressure. The cut-in point must not exceed 39,000 feet. Vary the altitude between 35,000 and 43,000 feet and record the outlet pressures indicated on the pressure-suction manometer at each altitude in table 18-2, using a flow of 10 ambient liters per minute and 100 ambient liters per minute. Repeat the above test with the oxygen inlet pressure set at 90 psig on the oxygen gage within the altitude chamber. The recorded pressures must be within the limits listed in table 18-2. The pressure drop in recorded outlet pressures at 50 psig and 90 psig inlet, for flows of 10 and 100 ambient lpm at each altitude, must not exceed 0.75 inches of water.

Table 18-2.—Maximum and minimum mask pressures.

Altitude (feet)	Mask Pressures (inches of water)	
	Min.	Max.
35,000		3.5
39,000		8.0
41,000	4.0	10.2
43,000	10.0	12.5

Maximum Pressure Control

Cap the pressure pickup tube in the regulator.

Set the oxygen inlet pressure on the oxygen gage within the altitude chamber at 70 psig. With an ambient flow of 10 lpm evacuate the chamber to 50,000 feet altitude. Record the outlet pressures at 0 and 10 ambient lpm from the pressure-suction manometer. The maximum pressure control point occurs when the pressure-suction manometer indicates a constant outlet pressure. The maximum pressure control must operate at 16 ±2 inches of water at 50,000 feet. The relief valve is the maximum pressure control device for this regulator.

EMERGENCY OXYGEN SYSTEM

The purpose of the emergency oxygen system is to administer breathing oxygen and suit pressure necessary for sustaining a crewmenber during high-altitude operations under emergency conditions. This equipment includes the oxygen supply bailout bottle and the pressure reducer.

There are a number of various types of oxygen bailout bottles. The testing procedures and testing intervals may be found in their appropriate Overhaul Instructions Manuals. This chapter will cover the Firewel oxygen bailout bottle and the suit mounted pressure suit controller.

The following test procedures for testing the suit mounted controller and the oxygen supply bailout bottle are conducted on the 62-A-116-E1 test stand.

SUIT MOUNTED CONTROLLER

The suit mounted controller is an aneroid controlled exhaust valve which monitors the rate of flow of exhaust gases from the suit to maintain an absolute suit pressure of 6.9 ±0.3 inches of mercury (equivalent to 35,500 ±1,000 feet). With a minimum of resistance, 300 lpm ventilation air can be exhausted while the suit is in the pressurized condition. A water check valve is incorporated into the controller unit. The controller is designed to mount directly to the existing exhaust port fitting on the Mk 4 full pressure suit.

Test Procedures

Test procedures for testing the suit controller are discussed in the following paragraphs.

11244

Insure that all test stand valves are closed. Cap the input tap and the air input tap. Connect a pressure suit exhaust port fitting to the controller test fixture. (See fig. 18-10.) Then connect the suit controller. Connect the controller test fixture directly to the piezometer and the hose from the piezometer to the reference tap 21 as shown in view A of figure 18-7. Place selector valve M to the controller position, 0 to the suit simulator position, valve D to HG position and L to off. Open valve R fully, and load the altitude controller B to 20 psi, using controller regulator P. Adjust the low-pressure regulator N to the 100 psig reading on gage 11. Regulate valve H to deliver 100 and 300 lpm to the suit controller. Read the pressure rise on the Hg manometer 5 at the given setting and record on the test sheet (fig. 18-11). Close valve H and relieve pressure on the low-pressure regulator N. Close the chamber door; turn the vacuum pump on, and ascend to 33,000 feet with valve B. Open valve I to deliver 100 and 300 lpm to the suit controller.

PR.395

Figure 18-10.—Controller test fixture.

Record controller hold pressure indicated as differential pressure on the Hg manometer 5. Open valve I to deliver 100 and 300 lpm to the suit controller. Read and record the suit pressure indicated on the Hg manometer 5 and the suit altitude on suit altimeter 13. Ascend to 80,000 feet with valve B. Read and record the controller hold altitude on suit altimeter 13; also record the controller hold pressure indicated as differential pressure on the Hg manometer 5. Remain at 80,000 feet for 5 minutes. The pressure drop must not be more than 0.2 inch of Hg below the original pressure recorded at the beginning of the 5-minute period. If the drop is greater, the controller is not serviceable. Descend to 40,000 feet by setting the B valve and opening the I valve. When 40,000 feet is reached, close valve I. Read and record the controller hold altitude on suit altimeter 13; also record controller hold pressure indicated as differential pressure on the Hg manometer 5. Open valve I to deliver 100 and 300 lpm to the suit controller. Read and record the suit pressure indicated on the Hg manometer 5 and the suit altitude on suit altimeter 13. Remain at 40,000 feet for 5 minutes. The pressure drop must not be more than 0.2 inch of Hg below the original pressure recorded at the beginning of the 5-minute period. If the drop is greater, the controller is not serviceable. Open valve I and descend to sea level. NOTE: Valve I must be open at all times when descending to insure that the Hg manometer 5 does not overflow. The Hg should be visible at all times. Secure from the test.

Read the pressure rise on the Hg manometer 5 at the given setting and record on the test sheet. Close valve I. Using valve B, ascend to 50,000 feet in 1 minute. The absolute suit pressure must be between the limits of 6.9 ±0.3 inches of Hg with no ventilating air supplied at any time. Read and record the controller hold altitude on suit altimeter 13; also record the controller hold pressure indicated as differential pressure on the Hg manometer 5. Ascend to 60,000 feet, using valve B. To obtain a true suit pressure hold condition when testing suit

controllers at various ambient altitudes, ventilation air must be induced (not to exceed 300 lpm ambient) for a few seconds and then shut off. Fifteen seconds after securing the ventilation air and the pressures have stabilized, the suit pressure must be recorded.

FIREWEL EMERGENCY BAILOUT BOTTLE

The Firewel emergency bailout bottle is horseshoe shaped and is designed to mount directly in the seat pan assembly. It will hold 50 cubic inches of oxygen at 1,800 psi. Figure 18-12 shows an exploded view of the bailout bottle.

The Firewel bailout bottle will be subject to the test described in the following paragraphs.

Leakage and Emergency Release Test

Secure the bottle assembly in the seat pan. Place the lever (12, fig. 18-12) to the OFF position, using a resetting tool and insert the pin (1, fig. 18-12). Connect the emergency release assembly to the pin. Charge the bottle to approximately 200 psi (adjacent to the letter "R" in the word "Refill") on the face of the pressure gage which is attached to the reducer. Attach a

spring scale to the green apple of the emergency release cable and pull. The retainer fastener should release at 20 ±5 pounds. Check the automatic release cable to release at 20 + 15 - 5 pounds. Recharge the bottle to 1,800 psi, pull the green apple, and release oxygen. Again charge the bottle to 1,800 psi. Disconnect the emergency release from the pin and remove the reducer and bottle assembly from the seat pan. Cap the fitting (2, fig. 18-12) and submerge the bottle assembly in water so that the housing attaching screws are covered, but not the nut. If bubbles appear, slowly raise the bottle assembly out of the water to determine the exact area of the leakage and correct accordingly. Dry the bottle thoroughly and mark the gage at the exact position of the indicating arrow. Tag the bottle with the date and hour and allow 72 hours to elapse. If the gage reads within 1/32 inch of the previous mark, the bottle is acceptable.

NOTE: rapid refilling of the emergency oxygen bottle causes severe internal heating and may result in an explosion or fire. Charge bottle pressure in accordance with table 18-3.

11248

CHAPTER 19

NES-8A PERSONNEL PARACHUTE ASSEMBLY

The NES-8A personnel parachute assembly is designed for use with an integrated torso suit harness and is part of the ejection seat escape system. This assembly includes a Skysail Model "E," multicolored, 29.7-foot diameter, ringsail canopy with 24 gores. The canopy is packed in a hardshell "horseshoe" type container and installed in the ejection seat.

The integrated torso suit harness combines the aircrewman's parachute harness and lap and shoulder restraint straps. The harness is channeled through the torso suit to retain it in position and to facilitate donning. When aboard the aircraft and seated, the aircrewman connects the quick-release fittings on the parachute riser assembly to the quick-release shoulder fittings on the integrated torso suit. The survival kit is also connected to the integrated torso suit by means of quick-release fittings.

OPERATION

After ejection, the drogue parachute is deployed from the ejection seat and pulls the withdrawal line assembly from the container assembly. When the withdrawal line reaches full stretch, the ripcord locking pins are removed from the locking cones, permitting the grommets, locking cones, and end tabs to disengage. The container spring bands pull the end and side flaps apart allowing the pilot parachute to spring from the container and fill with air. If the withdrawal line assembly fails to remove the ripcord locking pins, the parachute container can be opened by manually pulling the ripcord handle. In this case, only the pilot parachute will deploy the canopy.

The aircrewman falling away from the pilot parachute and drogue parachute causes the canopy to be pulled from the container assembly, followed by the suspension lines. The canopy begins to fill with air during this operation. The tape fasteners securing the lift webs to the container releases as load is applied. The lift webs are then pulled from the container assembly and the canopy opens fully.

The aircrewman hangs suspended in his harness from the quick-release shoulder fittings during descent. The antisquid lines may break during high-speed openings. Upon landing, the aircrewman can disengage the canopy and suspension lines from the integrated torso suit harness by using the quick-release shoulder fittings.

PACKING AND RIGGING

Lay out the canopy assembly full length on the packing table. Locate the canopy gore with the nameplate and place it uppermost. Separate the suspension lines into two equal groups, counting 12 suspension lines on each side of the nameplate gore. Place the connector link holding suspension lines 1 through 6 on top of the connector link holding suspension lines 7 through 12. Place the connector link holding suspension lines 19 through 24 on top of the connector link holding suspension lines 13 through 18. Connect these two pairs of connector links to their respective tension hooks on the packing board and insert them into the packing table. Insure that the knurled portions of the connector link yoke and the plate assemblies face up and that the screwheads face outboard.

Attach the antisquid lines, pilot parachute connector cord, and withdrawal line. (This is necessary only for original issue assemblies.) Using 10 pounds of tension, measure and cut a 68.5-foot length of 1,000-pound nylon cord, MIL-C-7515, type IV. Double the cord so that both halves are equal in length; mark the center of the cord. Wrap the loop end of the doubled antisquid line twice around the vent

11249

focusing and deflection are by an electromagnetic deflection. (NOTE: An electromagnetic CRT could employ electrostatic focusing.)

In this type CRT, the first anode (after the control grid) serves as the accelerating element rather than as the focusing device. The second anode (rather than being the accelerating anode as in the electrostatic CRT) is the aquadag coating with a high-positive potential applied to it. It serves the same purpose as aquadag coating in the electrostatic type CRT. However, it does aid in accelerating the electrons and may sometime be referred to as an accelerating anode.

The focusing coil of the electromagnetic CRT replaces the second anode and performs the same function as the first anode in the electrostatic CRT. The deflection coils, or deflection yoke as it is sometimes called, replaces and performs the same function as the deflection plates in the electrostatic type CRT. Figure 17-5 is an illustration of the complete basic electromagnetic CRT.

The focusing coil is essentially an electromagnet which fits around the neck of the CRT as illustrated in figure 17-6. When a d-c current flows through the windings of the coil, a magnetic field is set up, part of which is within the neck of the tube. It should be noted that within the neck the magnetic lines of force have a mean direction which is along the axis of the neck. Thus, the magnetic field causes the electron beam to converge. The amount of current in the coil may be controlled by a rheostat (focus control), thus controlling the strength of the magnetic field.

The manner in which the electron beam is focused may be explained with the aid of figure 17-6. Point P is the crossover point which the electron beam is assumed to have reached after being emitted by the cathode, acted upon by the grid, and accelerated by the first anode.

The electrons traveling down the axis of the tube will not be affected by the magnetic field. Those electrons traveling at a small angle will have a force applied to them perpendicular to the magnetic field. This force will tend to bring the electrons back into the line of travel. This action, however, could cause the electrons to oscillate back and forth across the neck of the tube and gradually damp out. As shown in figure 17-6, an electron traveling along the line PAB or PDE would be forced by the magnetic field to take the paths PACS and PDFS, respectively. All electrons coming from the crossover point P and entering the magnetic field follow paths that make them meet at the common point S.

However, it is possible that an electron could be traveling off to one side or the other as well as at an up or down angle. Thus, the magnetic field could be acting on the electrons in more

Figure 17-5. —Electromagnetic CRT.

1122

lines. Pass the cord ends through the loop. (See fig. 19-1.)

Pass the loop ends of the pilot parachute connector cord and withdrawal line through the two turns of the antisquid line and around the vent lines. Pass the pilot parachute through the loop in the end of the connector cord and pass the drogue link fittings through the loop in the end of the withdrawal line. (See fig. 19-2.)

Pull the pilot parachute connector cord, withdrawal line, and antisquid lines tight at the center of the vent lines. Route the antisquid line down the inside center of the canopy to the connector links. Insure that the antisquid lines are not twisted or routed through slots between the canopy sails. Secure one antisquid line between suspension lines 3 and 4 on one top connector link and the other antisquid line between suspension lines 21 and 22 on the other top connector link with a Chinese finger knot. Zigzag stitch through each knot with unwaxed size E nylon thread, single. Start 4 inches from the connector links and sew away from the connector links for a distance of 1 inch. (See fig. 19-3.)

SUSPENSION LINE CONTINUITY CHECK

To perform a continuity check, secure a loop of webbing around the vent lines, attach a strap hook to the loop and tighten. The packer and helper must grasp the canopy at the second set of sails and pull toward the canopy peak, applying tension to the suspension lines. The packer must start with suspension line number 1 on the left side of the nameplate gore and work through line 12.

The helper must be positioned at the connector links to check the suspension lines selected by the packer for continuity, dips, and twists. The same procedure is used on the right side of the nameplate gore, except that the packer will start with suspension line number 24 and work through line 13.

PR.398

Figure 19-1.—Antisquid line to apex.

ATTACHMENT OF CONNECTOR LINKS

Attachment of the suspension line connector links to the riser assembly and cross connector straps must be accomplished upon receipt of original issue.

Lay out the riser assembly and cross connector straps on the packing table. Corresponding lift webs must be placed on top of each other and positioned at the connector links. The ripcord assembly must face up. (See fig. 19-4.)

Remove the connector links from the tension hooks, and remove the connector link yoke and plate assembly from each connector link. Insert the bottom connector links through the loops in the corresponding bottom lift webs. Reattach the yoke and plate assemblies to the bottom connector links and tighten the screws to a torque value of 20 to 25 inch pounds; paint each screw with lacquer. (See fig. 19-5.)

Attach the top lift webs and cross connector strap to the top connector links in the same manner as described in the above paragraph. Insert the connector links into the tension hooks and tighten the tension strap at the canopy peak; recheck continuity of the suspension lines.

WHIPPING AND FOLDING THE CANOPY GORES

Route the suspension lines around the packing board spools. Tighten the packing board tension strap, applying tension to the suspension lines. (See fig. 19-6.)

NOTE: The radial tapes must run free from the skirt hem to the canopy peak. The tapes must not be twisted in the sails or around each other.

The packer and helper must lift the suspension line on each side of the nameplate gore

11250

PR.399

Figure 19-2.—Attachment of the canopy drogue withdrawal line and pilot chute bridle.

PR.400

Figure 19-3.—Attachment of antisquid lines to connector link.

up and out. The skirt hem between the lines should be taut so that the canopy peak can be seen on the inside. While holding the suspension lines up, each man will alternately whip the gores hanging from the suspension line outward to prepare the canopy for folding.

As each gore is whipped, the packer and helper must check to verify that the radial tapes run free to the canopy peak. Each man must alternately draw the next suspension line upward to the suspension line held in hand, using a rapid, circular motion. (See fig. 19-7.)

Upon completion of the whipping operation of all canopy gores, the two groups of suspension lines must be stretched to the edges of the packing table with folded gores hanging over the side. The packer must flap the top sail up and down at the skirt hem center, as the helper holds the bottom sail at the skirt hem center. On signal, both men must draw their respective sails, at centers, toward each other while at the same time bringing the suspension line groups to the center of the packing table.

Insert the suspension line groups into their respective slots in the suspension line separator. The packer and helper must fold the seventh set of sails to the suspension lines at table center, as shown in figure 19-8.

The packer and helper must straighten and smooth each sail when placing them back onto the packing table one at a time. There must be 12 sails on each side of the packing table.

S-fold the seventh set of sails, retaining the sails in the proper position by placing a shot bag on top of the S-folded sails. (See fig. 19-9.)

Straighten, smooth, and S-fold the next four sets of sails in the same manner. Straighten and smooth the top two sets of sails toward the

PR.401

Figure 19-4.—Layout of risers and cross connector straps.

apex in the same manner as the seventh set. Fold the second set of sails to the center of the canopy and hold them down with a shot bag. Hold the top set of sails in place by using a shot bag. (See fig. 19-10.)

STOWAGE OF SUSPENSION LINES

Remove the suspension lines from the packing board spools and S-fold them onto the packing table. Remove the canopy tension strap at the peak and remove the connector links from the tension hooks. Remove the packing board from the packing table as shown in figure 19-11.

Tie the outboard side of the connector links together with one turn of FF nylon thread, single.

11252
UCSII

PR.402

Figure 19-5.—Installation of the cross connector straps.

Position the stowage tray under the antisquid lines approximately 9 inches from the connector links. The stowage tray retaining angles must face up. Pull the canopy peak away from the stowage tray until the antisquid lines are taut. Place the antisquid lines between the fourth and fifth stowage channels from the outboard side of the stowage tray. There must be no slack in the antisquid lines between the connector links and the packing tray. (See fig. 19-12.)

The packer and helper must each pass a length of line stowage aid through the second outboard stowage channels and form a bight in the suspension lines, as shown in figure 19-13.

The packer and helper must draw the suspension line bights through the stowage channels to the edge of the packing tray. The second and third suspension line bights are stowed in the same manner as the first stow.

Remove the antisquid lines from their present position and route them along the outboard sides and top edges of the packing tray. Form the fourth suspension line bights and at this time include the first bight of the antisquid lines. (See fig. 19-14.)

The packer and helper must form and stow bights of suspension and antisquid lines in the same manner as previous stows.

PR.403

Figure 19-6.—Routing and tensioning of the suspension lines.

Turn the packing tray so the bottom of the tray faces the canopy. Stow the suspension line and antisquid line bights in the two center stowage channels as shown in figure 19-15.

Form and stow the suspension lines and antisquid line bights in the reamining stowage channels, working from the center of the packing tray to the outer edges. Remove the shot bag and separator from suspension lines as the canopy approaches the packing tray. There should be 17 to 19 inches between the canopy skirt hem and each outboard stowage channel when all stowage channels are filled. (See fig. 19-16.)

11253

PR.404

Figure 19-7.—Whipping the canopy.

PR.405

Figure 19-8.—Folding the seventh set of sails.

Turn the packing tray under so the bottom of the tray faces the risers and the retaining angles face up. Rotate the risers and connector links over the packing tray and stow any excess suspension lines into stowage channel number 1.

ATTACHMENT OF STOWAGE TRAY AND RISERS TO THE CONTAINER

Position the container on the packing table, aft of the stowage tray, so that the side flap containing the locking cones is uppermost and the open end of the container faces the canopy. Slide the container toward the canopy, inserting the stowage tray into the container. Do not move the stowage tray toward the container. Insure that the suspension lines do not become trapped under the tray retaining angles. The pilot parachute kickplate must not be wedged between the stowage tray and the container.

Aline the threaded holes in the stowage tray retaining angles with the holes located in the bottom of the container legs.

Aline the brackets on the container retention straps above the holes in the bottom of the container legs. Insert the screws through the washers, retention strap brackets, and the holes in the container legs. Thread the screws into the retaining angles and tighten. Insure that the retention strap bracket is turned upward as shown in figure 19-17.

Place the container into a container stand. (See fig. 19-18.)

Attach the hook tape patches on the risers to the pile tape patches on the inside of the container, as shown in figure 19-19.

STOWAGE OF THE CANOPY

Remove the shot bags from the three sets of sails closest to the skirt hem. The packer and helper must fold the skirt hem under 4 inches and tuck into the container legs. The excess suspension line must be stowed in each respective container leg. Remove the remaining shot bags from the folded sails.

NOTE: The canopy sails are numbered 1 through 7, starting from the canopy peak to the skirt hem.

GGA11254

PR.406

Figure 19-9.—S-folding the sails.

Accordion-fold sail sets 7, 6, and 5 into the container legs. Accordion-fold the remainder of the canopy lengthwise across the top of the container so the peak is positioned at the helper's end of the container. Press each accordion fold into the container separately. (See fig. 19-20.)

PR.407

Figure 19-10.—Sail folding of canopy completed.

CLOSING OF THE CONTAINER

Pull the side flap with locking cones over the top of the folded canopy. Pull the side flap with grommets over the top side flap with locking cones and place the grommets over the locking cones. Insert the temporary locking pins.

Remove the temporary locking pins on the packer's side and place the grommet on the end flap over the locking cone between the side flaps.

Place the side flap grommet back over the locking cone and place the metal end tab over the grommet and locking cone. Reinsert the temporary locking pin as shown in figure 19-21.

S-fold the withdrawal line under the side flaps on the helper's end. Insure that the pilot parachute cloth is not twisted around or entangled in the compressed pilot parachute spring.

Insert the guide tube through the grommet in the crown of the pilot parachute and place it over the locking cone on the spring baseplate. Compress the pilot parachute fully, remove the guide tube, and insert the pilot parachute temporary locking pin into the locking cone hole.

11255

PR.408

Figure 19-11.—S-folding of the suspension lines.

PR.409

Figure 19-12.—Antisquid lines and suspension lines positioning.

Place the pilot parachute kickplate on top of the canopy peak and withdrawal line and S-fold the pilot parachute connector cord over the kickplate. Tuck the pilot parachute cloth under the pilot parachute crown and place the pilot parachute over the folded connector cord. The withdrawal line must exit from the rear of the helper's end flap.

Remove the temporary locking pin on the helper's side and pull the end flap over the compressed pilot parachute. Route the withdrawal line out the rear of the container, remove the grommet side flap from the locking cone, and place the grommet on the end flap over the locking cone. Replace the side flap grommet over the locking cone. Place the end tab over the locking cone and reinsert the temporary locking pin.

Remove the pilot parachute temporary locking pin and insert the riser protector flaps, using a packing fid.

Insert the ripcord anchor plate through the webbing loop on the end flap. The manual ripcord cable must pass over the loop. The helper must hold the end tab over the locking cone on the withdrawal line end of the container and the packer must remove the temporary locking pin. The packer must position the anchor plate over the locking cone and insert the temporary locking pin.

11256

PR.410

Figure 19-13.—Stowing of the suspension lines.

PR.411

Figure 19-14.—Stowing the antisquid and suspension lines.

Route the ripcord pin line through the alinement ring on the end flap. Insert the curved ripcord pin through the eye on the end of the manual ripcord cable. The helper must insert the curved ripcord pin in the locking cone nearest the anchor plate as the packer removes the temporary locking pin. Insert the straight ripcord pin into the second locking cone in the same manner.

Safety-tie the straight ripcord pin using size A nylon thread, unwaxed. Secure the pin by tying 3 to 4 half-hitches around the ripcord cable.

The curved pin must pass through the eye of the ripcord cable. The locking ring is installed on the locking cone and the locking pin must be inserted through the locking cone. The locking lanyard and ripcord pin line must pass through the alinement ring.

Route the locking lanyard through the alinement ring, place the locking ring over the locking cone, and insert the locking pin into the locking cone. Safety-tie the locking pin by passing a length of unwaxed size A nylon thread, single, under the end of the pin and through the loop formed by the end of the pin. Tie the ends with a surgeon's knot followed by a square knot. (See fig. 19-22.)

Close the ripcord protector flap, remove the container from the stand, and attach four container spring opening bands (two on each end of the container). Crimp the hook at the container end to the eyelet. Do not crimp the flat end hook. Position the risers on top of the container and mate the hook and pile tape patches.

Fill out and sign the parachute record card and parachute history card. Insert the GND/AIR emergency code form and parachute record card into the packing data card pocket located on the ripcord pin protector flap.

NOTE: Collateral duty inspection is a mandatory requirement in parachute packing and rigging procedures. As each phase is completed, all work must stop until a collateral duty inspector has performed the inspection.

11257

11259

Figure 17-6. —Electromagnetic focusing.

than one direction at one time, which would effectively result in a spiral path of travel by the electrons, as illustrated in figure 17-7. If you could look down on the face of the scope and see the paths of the electrons you would see spirals such as these. Spiral (A) is the path of an electron that entered the magnetic field at a greater angle than in spiral (B). However, it travels faster and they both reach point S at the same time. In order to focus the beam, it is only necessary to adjust the strength of the magnetic field so that the common point S falls on the fluorescent screen.

Although we have considered using only electromagnets for focusing, a permanent magnet can perform the function equally as well. Some CRT indicators utilize permanent magnet focusing devices. The permanent magnet encircles the neck of the CRT in a manner similar to the focusing coil. Focusing of the electron beam is accomplished by moving the magnet along the axis of the tube until the beam of electrons is sufficiently concentrated at the face. Another means of adjusting the focus of an electron beam with a permanent magnet would require the use of a shunt. The shunt would be adjusted to increase or decrease the concentration of magnetic flux in the neck of the CRT.

Figure 17-7. —End view of the paths of the electrons.

Electromagnetic deflection is sometimes more desirable and offers some advantages over electrostatic deflection. One big advantage is that tube construction is simpler since there are no deflection plates within the tube. Another advantage is that high amplitude deflection voltages are not required since it is a current operated device.

To understand electromagnetic deflection of an electron beam in a CRT, it is essential that the Aviation Electronics Technician understand the properties and characteristics of current carrying conductors, their magnetic fields, and the interaction between two or more magnetic fields.

The electromagnetic deflection method most commonly used employs the stationary deflection yoke. A schematic of the yoke is shown in figure 17-8.

As illustrated, the deflection yoke consists mainly of an iron core and two sets of deflection coils mounted at right angles to each other.

11263

CHAPTER 20

NES-8B PERSONNEL PARACHUTE ASSEMBLY

The NES-8B parachute assembly includes a multicolored, 28-foot diameter, flat, circular nylon canopy with 28 gores and a pilot parachute. The canopy is packed in a hardshell horseshoe type container for installation in an ejection seat. The NES-8B is used with an integrated torso suit harness which combines the aircrewman's parachute harness and lap and shoulder restraint straps. The harness is channeled through the torso suit to retain it in position and to facilitate donning.

When aboard the aircraft and seated, the aircrewman connects the quick-release fittings on the parachute riser assembly to the quick-release shoulder fittings on the integrated torso suit. The survival kit is also connected to the integrated torso suit by means of quick-release fittings.

The NES-8B parachute assembly is shown in figure 20-1.

OPERATION

After ejection, the ejection seat drogue gun fires a piston which deploys a controller drogue parachute. The controller drogue parachute, in turn, deploys the stabilizer drogue parachute. The stabilizer drogue parachute remains attached to the seat by a scissor shackle.

The scissor shackle is released at a preset altitude by the operation of the time release mechanism, and the aircrewman separates from the seat during this operation. When the stabilizer drogue parachute releases from the seat, it pulls the withdrawal line assembly from the container assembly. As the withdrawal line reaches full stretch, the ripcord locking pins are removed from the locking cones, permitting the grommets, locking cones, and end tabs to disengage. The container spring opening bands pull the end and side flaps apart, allowing the pilot chute to spring from the container and fill with air.

Should the ejection seat time release mechanism fail to operate, the aircrewman can manually disengage himself from the seat by pulling the emergency harness release handle. In this case the guillotine assembly will cut the withdrawal line securing the drogue parachutes to the pilot chute. The aircrewman must then push himself clear of the seat and pull the manual ripcord handle, deploying the pilot parachute which deploys the canopy.

The aircrewman falling away from the pilot parachute and drogue parachute causes the canopy to be pulled from the container assembly, followed by the suspension lines. The canopy starts to fill with air during this operation.

As load is applied, the riser fasteners are released and the lift webs are then pulled from the container assembly.

The connector link ties break and the canopy fully opens. The aircrewman hangs suspended

PR.420

Figure 20-1.—NES-8B parachute assembly.

GOSII 11264

in his harness from the quick-release shoulder fittings during descent.

Upon landing, the aircrewman can disengage the canopy and suspension lines from the integrated torso suit harness by using the quick-release shoulder fittings.

NOTE: The pulldown vent lines may break during high speed openings.

MODIFICATIONS AND UPDATING

The NES-8B personnel parachute assembly must be modified and updated when required by comparing the configuration of the assembly with applicable directives and NavAir 13-1-6.2.

Compliance with modifications to the NES-8B parachute assembly must be performed by intermediate or depot levels of maintenance. All modifications must have the information recorded on the parachute history card and other records in accordance with NavAir Instruction 4700.2.

RIGGING AND PACKING THE NES-8B PARACHUTE

Lay out the canopy assembly full length on a clean packing table. Locate the canopy gore containing the nameplate and position it uppermost in the center of the packing table. Separate the suspension lines into two equal groups, counting 14 suspension lines on each side of the nameplate gore. The vent lines must be equally divided on each side of the nameplate gore.

The two groups, of 14 suspension lines each, are arranged as shown in figure 20-2. The numbers in figure 20-2 illustrate the location and orientation of the suspension lines as attached to the skirt hem and the connector links.

Place the connector link holding suspension lines 1 through 7 on top of the connector link holding suspension lines 8 through 14. Place the connector link holding suspension lines 22 through 28 on top of the connector link holding suspension lines 15 through 21. Connect these two groups of connector links to their respective tension hooks on the packing table.

NOTE: Insure that the knurled portions of the connector link yoke and plate assemblies face up and the screwheads face outboard.

PR.421

Figure 20-2.—Suspension line continuity.

SUSPENSION LINE CONTINUITY CHECK

Attach the tension strap to the canopy vent lines and tighten. When viewed from the riser end of the packing table, the suspension lines must be arranged on the skirt hem and the connector links in accordance with figure 20-2. They must run from the skirt hem of the canopy to the connector links without dips or twists.

NOTE: On other than original issue parachutes, the pulldown vent (PDV) lines, risers, and the cross connector straps will be already attached to the connector links.

The packer, starting with suspension line 1 on the left side of the nameplate gore, must work through line number 14. The helper must be positioned at the connector links to check the suspension lines selected by the packer for continuity, dips, and twists. The same procedure is used on the right side of the nameplate gore, except that the packer will start with suspension line 28 and work through line number 15. If attached, the PDV lines are connected at the top connector links between lines 3 and 4 and lines 25 and 26, as applicable. They must run under the top suspension lines to the type III cord without twisting around any suspension line.

WHIPPING AND FOLDING THE CANOPY GORES

NOTE: During the rigging and packing procedures, the packer is positioned on the left side of the packing table and the helper is on the right when facing the canopy from the harness/riser end of the packing table.

Insure that the tension strap is tightened at the canopy peak. The packer and helper must lift the suspension line on each side of the nameplate gore up and out. The skirt hem between lines should be held taut so that the canopy peak can be seen from the inside. While holding the suspension lines up, each man whips the gore hanging from the suspension line outward

11265

to prepare the canopy for folding. (See fig. 20-3.)

Draw the next suspension line upward to the suspension line held in the hand, using a rapid, circular motion as shown in figure 20-4.

Continue whipping and folding the remaining gores. Move the gores rapidly back and forth across the packing table, insuring that no radial seams are overlapped by any gores.

The two groups of suspension lines must be stretched to the edges of the packing table with the folded gores hanging over the sides. The packer and helper must grasp all the folds at the outer edges on the skirt hem and hold the suspension line groups at the edges of the packing table. The packer and helper should simultaneously move the folds up and down rapidly, in a whipping motion, to eliminate any wrinkles.

PR.422

Figure 20-3.—Whipping a canopy gore.

PR.423

Figure 20-4.—Folding a canopy gore.

The packer flaps the top gore up and down at the skirt hem center as the helper holds the bottom gore at the skirt hem center. On signal, both men must draw their respective gores, at the skirt hem centers, toward the table edge, while at the same time bringing the suspension line groups to the center of the packing table.

The suspension line groups are inserted into their respective slots in the suspension line separator and a shot bag is placed on the lines. The packer places a second shot bag across the skirt hem on the left side of the suspension lines, and the PDV lines are routed underneath the suspension line separator.

The helper now rotates all gores as a group, except the bottom gore, from the right over to the left side of the packing table. The helper must straighten and smooth the bottom gore on the right side of the packing table throughout its length to the peak. The packer returns the folded gores above the shot bag to the right side of the packing table and the helper straightens and smooths the top gore and places the bag on the skirt hem.

The packer must rotate all gores as a group, except the bottom gore, from left over to the right side of the packing table. The packer straightens and smooths the bottom gore on the left side of the packing table throughout its length to the peak. The helper returns all folded gores above the shot bag to the left side of the packing table and the packer straightens and smooths the top gore.

The packer and helper grasp the skirt hem at midsections of the gores and rotate towards the suspension lines. Each fold must be alined and counted when placed back onto the packing table.

The skirt hem must be made neat by having all "V" tab reinforcements alined in the same direction on top of each other. Each group of folds on the left and right of suspension lines must contain 14 gores.

The packer and helper grasp the skirt hem and folded gores and S-fold the canopy towards the center. Butt the S-folds together. The canopy cannot be S-folded throughout its entire length, but will break at a point approximately two-thirds of the distance to the peak, as shown in figure 20-5.

11266

PR.424
Figure 20-5.—Canopy S-folded.

PR.425
Figure 20-6.—Drawing the canopy down the table.

SUSPENSION LINE STOWAGE

Remove the tension strap from the canopy peak but not from the PDV line tension cord.

The helper must grasp only the suspension lines, not the PDV lines, 14 1/2 feet from the connector links and spread each group to the edge of the packing table. (See fig. 20-6.)

While the helper holds the suspension lines at the edges of the table, the packer draws the canopy down the center of the packing table, between the suspension lines, to a point where the suspension lines between the helper's hands and the skirt hem become taut. At this point the PDV lines will protrude through the vent hem. If the PDV lines do not appear at the vent hem, the packer must pull the canopy further down the packing table until they do.

Position the stowage tray under the suspension lines 5 inches from the connector links, with the retention angles turned upward as shown in figure 20-7.

Remove the type III nylon cord from the angles turned upward and remove the PDV lines at the canopy peak.

The packer and helper must each pass a length of stowage aid line through the outboard stowage channels and form the first bight in the suspension lines. Do not stow the PDV lines. (See fig. 20-8.)

The packer and helper must draw bights through the outboard channels to the edge of the stowage tray. Continue stowing the suspension lines to the center of the tray, excluding the PDV lines. Do not stow the two center stowage tray channels. (See fig. 20-9.)

11267

PR.426

Figure 20-7.—Stowage tray positioning.

PR.428

Figure 20-9.—Suspension lines stowed to tray center.

PR.427

Figure 20-8.—Forming the first bight of suspension lines.

Turn the stowage tray toward the canopy so that the retention angles face down, as shown in figure 20-10.

Begin stowing the suspension lines in the number six stowage channels, counting from the outboard edges of the tray. Do not stow the PDV lines. (See fig. 20-11.)

Continue stowing suspension lines to the outboard edges of the tray. Begin stowing the PDV lines in the third stowage channels from the outboard edges of the stowage tray, as shown in figure 20-12.

When the stowage channels are filled, there should be approximately 18 inches of line between the stowage tray and the canopy skirt hem. (See fig. 20-13.)

ATTACHMENT OF PILOT PARACHUTE CONNECTOR CORD, WITHDRAWAL LINE, AND PULLDOWN VENT LINES

Pass the pilot parachute connector cord around the vent lines and through the loops in the ends of the PDV lines. Pass the pilot parachute through the loop in the ends of the connector cord and draw tight. Pass the loop end of the withdrawal line around the vent lines and through the PDV lines to the left of the pilot

11268

Figure 17-8. —Basic illustration of a stationary deflection yoke.

One set provides vertical deflection of the electron beam and the other horizontal deflection. Each coil is composed of many turns of wire, and the coils of each set are connected so that the magnetic fields set up by each pair of coils travel in the same direction and parallel across the neck of the CRT.

The two coils of each set are wound in series opposition to each other on the iron core. Thus, since the flux produced by each is in opposition (within the iron core), the only way in which the lines of force can form closed loops is by crossing the neck of the CRT. By using two sets of coils in this manner, two magnetic fields can be set up across the neck of the CRT which are at right angles to each other. Figure 17-9 is an illustration of the two sets

Figure 17-9. —(A) Vertical deflection; (B) horizontal deflection.

of deflection coils and their respective magnetic fields.

In both (A) and (B) of figure 17-9 it should be noted that the electron beam is coming out of the paper. Thus, the magnetic field around the beam is moving clockwise. As shown in (A) of figure 17-9, the magnetic flux set up

USN 1124

PR.432

Figure 20-13.—Stowage tray filled.

PR.433

Figure 20-14.—Attachment of pilot parachute connector cord, withdrawal line, and pulldown vent lines.

angles face up and the rounded end of the tray is turned away from the canopy. Position the container on the table with the open end facing the tray and the side flap containing the ripcord protector flap facing the packing table, as shown in figure 20-15.

4. Slide the container toward the canopy, inserting the stowage tray into the container. Do not move the tray toward the container. Insure that the suspension lines do not become trapped under the tray retaining angles. The pilot parachute kickplate must not be wedged between the stowage tray and container.

5. Aline the threaded holes in the stowage tray retaining angles with the holes in the bottom of the container legs. Aline the brackets on the container retention straps above the holes in the bottom of the container legs. Insert screws through the washers and retention strap brackets and the holes in the container legs. Thread the screws into the retaining angles and tighten. Insure that the retention strap bracket is turned upward. (See fig. 20-16.)

6. Place the container in the container stand. Attach the hook, tape patches on the risers to the pile tape patches on the inside of the container. Stow the line between the connector links and stowage tray in the bottom of the container legs. Stow the line between the stowage tray and canopy skirt hem behind the stowage tray, as shown in figure 20-17.

CANOPY STOWAGE

To stow the parachute canopy in the container, proceed as follows:

1. Remove the shot bag from the skirt hem.

2. Spread the suspension line groups approximately 6 inches and fold the skirt hem under 4 inches. Place the folded skirt hem on top of the container. Press the folded skirt hem firmly down into respective legs of the container. (See fig. 20-18.)

3. Accordion-fold all but approximately 6 feet of the canopy into the container. Separately

press each accordion fold firmly into the legs of the container. Accordion-fold the remainder of the canopy on the packing table, starting with the first fold on the packer's side and ending with the canopy peak on the kickplate side of the container. The accordion folds must extend 3 inches over the side of the container.

4. Position the accordion-folded canopy on top of the container. Insure that the canopy peak is positioned at the kickplate side of the container. Route the withdrawal line to the rear center of the container and back toward the pack. The ripcord pins must face up.

CLOSING THE CONTAINER

Pull the side flap with the locking cones over the top of the folded canopy. Pull the side flap with the grommets over the top side flap containing the locking cones and place the grommets over the locking cones. Insert the temporary locking pins into the locking cones from the proper direction.

Remove the temporary locking pin located on the packer's side and place the grommet on the end flap over the locking cone, between the side flaps.

Place the side flap grommet back over the locking cone and place the metal end tab over the grommet and locking cone. Reinsert the temporary locking pin.

Insert the guide tube through the grommet in the crown of the pilot parachute and place it
